Abstract. We consider the setting in which an untrusted server stores a collection of data and is asked to compute a function over it. In this scenario, we aim for solutions where the untrusted server does not learn information about the data and is prevented from cheating. This problem is addressed by verifiable and private delegation of computation, proposed by Gennaro, Gentry and Parno (CRYPTO'10), a notion that is close to both the active areas of homomorphic encryption and verifiable computation (VC). However, in spite of the efficiency advances in the respective areas, VC protocols that guarantee privacy of the inputs are still expensive. The only exception is a protocol by Fiore, Gennaro and Pastro (CCS'14) that supports arithmetic circuits of degree at most 2. In this paper we propose new efficient protocols for VC on encrypted data that improve over the state of the art solution of Fiore et al. in multiple aspects. First, we can support computations of degree higher than 2. Second, we achieve public delegatability and public verifiability whereas Fiore et al. need the same secret key to encode inputs and verify outputs. Third, we achieve a new property that guarantees that verifiers can be convinced about the correctness of the outputs without learning information on the inputs. The key tool to obtain our new protocols is a new SNARK that can efficiently handle computations over a quotient polynomial ring, such as the one used by Ring-LWE somewhat homomorphic encryption schemes. This SNARK in turn relies on a new commit-and-prove SNARK for proving evaluations on the same point of several committed polynomials. We propose a construction of this scheme under an extractability assumption over bilinear groups in the random oracle model.

1 Introduction

Due to the ubiquity of the Internet and the advent of cloud computing, it is increasingly common for users to exchange and receive information processed on remote machines. Online storage services are already widely available on the Internet, and allow users to store, access and share their data from anywhere and from multiple devices. This phenomenon includes not only storage: it is more and more common to rely on computation performed on third party machines.

While this shift in the computing trend brings several benefits, new security challenges also emerge. These challenges are related to a main question: *what happens if the remote machine is not trusted?* In this work we are particularly concerned with two security problems in this space. First, we would like to ensure that the untrusted machine can perform the computation without learning the private data of the users. Second, we would like to enable the receivers of computation results to efficiently check that such results are correct. Both problems are in the scope of two important research lines in cryptography.

Privacy-Preserving Computation. The first problem is related to fully homomorphic encryption (FHE) [RAD78, Gen09]. While for a long time it was only known how to construct homomorphic encryption schemes supporting a single operation (e.g., only addition [Pai99] or multiplication [ElG84]), Gentry's breakthrough showed the first FHE scheme that enables computing any function on encrypted data. If Gentry's first FHE was mostly a feasibility result, research in this area has progressed significantly giving rise to many new FHE schemes (e.g., [SV10, BV11, BGV12, GSW13, DM15, CGGI16, CGGI17]) that are efficient and see their first practical applications.

Ensuring Correctness of Computation. The second problem is related to verifiable computation (VC) [GGP10] and related notions such as interactive proofs [GMR85], probabilistically checkable proofs [AS92] and succinct arguments [Kil92]. Briefly speaking, these are protocols that enable a powerful prover to convince a verifier that a statement (e.g., correctness of a computation, $y = f(x)$) is true in such a way that the verifier can run with fewer resources, e.g., faster than re-executing the function. Similarly to FHE, also in this research area, results have been confined to theory for long time. However, several recent works have shown a change in this trend, and today we have several VC protocols that are efficient and have been experimented in practical scenarios, see e.g., [GKR08, CMT12, GGPR13, PHGR13, BCG⁺13, Gro16, ZGK⁺17, WJB⁺17, AHIV17, WTs⁺18, BCG⁺18, BBC⁺18, BCR⁺19, MBKM19, CFQ19, XZZ⁺19].

1.1 Ensuring Correctness of Privacy-Preserving Computation

In spite of the research mentioned above, the problem of ensuring both the correctness and the privacy of computation performed on untrusted machines has received much less attention in the literature. There are three main works that considered explicitly this problem.

The first one is the seminal paper of Gennaro et al. [GGP10] who introduced the notion of non-interactive verifiable computation. In [GGP10] they indeed show how to combine garbled circuits and FHE in order to build a VC scheme for arbitrary functions that also preserves the privacy of the computation's inputs and outputs against the computing machine.

The second work is that of Goldwasser et al. [GKP⁺13] that shows how to use their succinct single-key functional encryption scheme in order to build a VC protocol that preserves the privacy of the inputs (but not of the outputs).

Both these two solutions [GGP10, GKP⁺13] are however not very satisfactory in terms of efficiency. The main issue in the construction of [GGP10] is that they need the full power of FHE to perform homomorphic evaluations of garbled circuits. Some of the efficiency issues in [GKP⁺13] include the use of several instances of an attribute-based encryption that must support an expressive class of predicates (at NC1 circuits), and an inherent design limitation (due to following the approach of [PRV12]) by which their scheme supports functions with a single bit of output (which in practical scenarios like computing on large integers would require multiple instances of their protocol).

A third work that considered the problem of ensuring correctness of privacy-preserving computation is the one of Fiore et al. [FGP14] who proposed a solution that combines an FHE and a VC scheme. The idea of their generic construction is rather simple and consists into using a VC in order to prove that the homomorphic evaluation on ciphertexts has been done correctly. As discussed in [FGP14], even this solution may encounter efficiency limits. This is due to the fact that the VC scheme must be executed on a computation that, due to the FHE ciphertext expansion, is of much larger representation than the computation that would be executed on plain text. Motivated by this issue, [FGP14] also proposed an efficient solution that, for the case of quadratic functions, can avoid this issue. The efficient construction in [FGP14] overcomes the problem of ciphertext expansion in two ways: (1) they consider homomorphic encryption schemes working in the Ring-LWE setting in which ciphertexts are represented by polynomials in a given polynomial ring; (2) they develop, as the VC building block, an homomorphic MAC scheme especially tailored to handle messages that are polynomials in which the prover execution can be independent of the degree of such polynomials. However, for reasons that we will detail later (see Section 3), their technique is inherently bound to computations of multiplicative depth 1. Also, by using an homomorphic MAC as VC, verification requires a secret key, the same secret key used to encode the inputs. This limits the applicability of these solutions to scenarios where users and verifiers are either the same entity or they share a secret key.

1.2 Our Contributions

We propose a new protocol for verifiable computation on encrypted data that improves on the state-of-the-art solution of Fiore et al. [FGP14] in multiple aspects. Notably, we can support HE computations of multiplicative depth larger than 1. Second, we achieve public verifiability whereas [FGP14] is only privately verifiable. Finally, our scheme has an additional property that guarantees that verifiers may be convinced of outputs correctness without learning information on the original inputs. This latter property is particularly relevant in the publicly verifiable setting where the users who encrypt the data and the verifiers are distinct entities. Technically, we achieve this property because our protocol allows for re-randomizing the encrypted results, which was not possible in [FGP14] that only considered deterministic HE evaluations.

Our key tool to obtain this result is a new SNARK that can efficiently handle computations that are arithmetic circuits f over a quotient polynomial ring $\mathbb{R}_q := \mathbb{Z}_q[X]/\langle R(X) \rangle$ (exactly like the popular choice for many Ring-LWE schemes) in which the prover's costs have a minimal dependence on the degree d of $R(X)$. Specifically, let f be the circuit over \mathbb{R}_q and \hat{f} be the corresponding circuit over \mathbb{Z}_q (i.e., the one that would be computed on plaintexts where additions and multiplications in \mathbb{R}_q are replaced by the corresponding operations in \mathbb{Z}_q). Then, whereas a naive application of [FGP14]'s generic solution would incur a cost for proof generation at least $O(d \cdot |\hat{f}|)$ where $|\hat{f}|$ is \hat{f} 's circuit size, our scheme lets proof generation be doable in time $O(d \cdot n + |\hat{f}|)$ where n is \hat{f} 's input size. We stress that here we are considering the cost of proof generation, after having performed the HE computation; or in other words we consider the cost of generating the proof once the witness is available. To see how this efficiency feature concretely improves, consider for example an \hat{f} that is a multivariate polynomial of degree $c \geq 2$ by which $|\hat{f}|$ can be n^c , and consider that for Ring-LWE security the degree d can be a rather large integer (e.g., $d \approx 8000$). Then removing the multiplicative factor $d \cdot |\hat{f}|$ can significantly speed up the prover's costs. Let us also notice that the factor $d \cdot n$ is unavoidable as the prover must read the input.

Our SNARK for arithmetic circuits over polynomial rings is built in a modular way using two building blocks: a commit-and-prove SNARK for arithmetic circuits (AC- Π), and a commit-and-prove SNARK for multiple polynomial evaluations (MUniEv- Π).

To instantiate AC- Π , we can use any commit-and-prove SNARK for arithmetic circuits that supports the same commitment key as our scheme MUniEv- Π . Given the recent result of Campanelli et al. [CFQ19], MUniEv- Π can be instantiated with a variety of schemes including the efficient commit-and-prove variant of Groth16 [Gro16] proposed in [CFQ19].

For scheme MUniEv- Π , we propose a construction based on the Strong Diffie-Hellman and Power Knowledge of Exponent (PKE) assumptions in bilinear groups, in the random oracle model. We believe this scheme can also have other applications. Slightly more in detail, MUniEv- Π allows one to prove the following statement: given a commitment C to ℓ degree- d polynomials $\{P_j(X)\}_j$, a commitment C' to a vector of ℓ \mathbb{Z}_q -elements $\{p_j\}_j$, and a public point k , show that $p_j = P_j(k)$ for all $j = 1$ to ℓ . In comparison to using an existing general-purpose commit-and-prove SNARK for arithmetic circuits (e.g., LegoGroth16 from [CFQ19]), our scheme MUniEv- Π has slightly smaller proofs and proving time at least three times faster (cf. Section 7.3 for more details).

Finally, we note that our scheme MUniEv- Π is in turn constructed from a SNARK BivPE- Π for the partial evaluation of a committed bivariate polynomial, i.e., given commitments C and C' to $P(X, Y)$ and $Q(Y)$ respectively, prove that $Q(Y) = P(k, Y)$ for some public point k . We construct BivPE- Π by extending the univariate polynomial commitment techniques of Kate et al. [KZG10]. It is worth mentioning that other works [PST13, ZGK⁺17] extended [KZG10] to support the evaluation of multivariate polynomials, which include bivariate ones. However, the main difference (crucial for our application) is that we can support *partial* evaluations in one variable while keeping the result polynomial also committed.

1.3 Organization

In Section 2 we introduce notation and basic cryptographic definitions. Section 3 describes our SNARK for arithmetic computations in quotient polynomial rings. In Section 4 we show how to combine our SNARK from Section 3 together with Ring-LWE-based HE schemes in order to build a verifiable computation scheme with input and output privacy, and also how to achieve the new property of preserving privacy of the inputs from the verifier. In Section 5 we state the computational assumptions needed by our schemes, and we present the BivPoly.Com commitment. In Section 6 we build our SNARK $\text{BivPE-}\Pi$ for bivariate polynomials partial evaluation and then in Section 7 we show how turn it into an efficient $\text{MUniEv-}\Pi$ for the simultaneous evaluation of many univariate polynomials. In Section 8 we prove the security of our scheme $\text{BivPE-}\Pi$.

2 Notation and Definitions

Notation. Let $\lambda \in \mathbb{N}$ be the computational security parameter. We say that a function is *negligible* in λ , and we denote it by negl , if it is a $f(\lambda) = o(\lambda^{-c})$ for every fixed constant c . We also say that a probability is *overwhelming* in λ if it is $1 - \text{negl}$. When sampling uniformly at random the value a from the set S , we employ the notation $a \leftarrow_s S$. When sampling the value a from the probabilistic algorithm M , we employ the notation $a \leftarrow M$. We use $:=$ to denote assignment. We consider NP binary relations \mathcal{R} between statements u and witnesses w .

An adversary is denoted by \mathcal{A} and is assumed to be probabilistic Turing machines that run in polynomial time, i.e., PPT. For two PPT machines A, B , with the writing $(A\|B)(x)$ we denote the execution of A followed by the execution of B on the same input x and with the same random coins.

2.1 Commitment Schemes

For completeness, we recall the definition of a knowledge commitment scheme:

Definition 1 (Non-Interactive Commitment). A non-interactive commitment scheme is a tuple of algorithms $\text{Com} = (\text{ComGen}, \text{Com}, \text{ComVer}, \text{OpenVer})$:

- $\text{ComGen}(1^\lambda) \rightarrow \text{ck}$: Generates a commitment public key ck . It specifies a message space M_{ck} , a randomness (opening) space R_{ck} , and a commitment space C_{ck} . This algorithm is run by a trusted or distributed authority;
- $\text{Com}(\text{ck}, m) \rightarrow (c, o)$: Outputs a commitment c and an opening information o . Given a message $m \in M_{\text{ck}}$, the sender picks a randomness $o \in R_{\text{ck}}$ and computes the commitment (c, o) .
- $\text{ComVer}(\text{ck}, c) \rightarrow 0/1$: Checks whether c is a well-formed commitment. If so, it outputs 1, otherwise it outputs 0;
- $\text{OpenVer}(\text{ck}, c, m, o) \rightarrow 0/1$: Outputs 1 if the value $m \in M_{\text{ck}}$ is the committed message in the commitment c and 0 if (m, o, c) does not correspond to a valid pair opening-commitment.

We say $\text{Com} = (\text{ComGen}, \text{Com}, \text{ComVer}, \text{OpenVer})$ is a secure commitment scheme if it satisfies the following properties:

Correctness. Let $\text{ck} \leftarrow \text{ComGen}(1^\lambda)$. Any commitment of $m \in M_{\text{ck}}$ honestly generated $(c, o) \leftarrow \text{Com}(\text{ck}, m)$ is successfully verified by $\text{ComVer}(\text{ck}, c)$ and by $\text{OpenVer}(\text{ck}, c, m, o)$.

Hiding. It is statistically hard, for any adversary \mathcal{A} , to generate two messages $m_0, m_1 \in M_{\text{ck}}$ such that \mathcal{A} can distinguish between their corresponding commitments c_0 and c_1 where $(c_0, o_0) \leftarrow \text{Com}(\text{ck}, m_0)$ and $(c_1, o_1) \leftarrow \text{Com}(\text{ck}, m_1)$.

Binding. It is computationally hard, for any adversary \mathcal{A} , to come up with a collision (c, m_0, o_0, m_1, o_1) , such that o_0 and o_1 are valid opening values for two different pre-images $m_0 \neq m_1$ for c . For any adversary \mathcal{A} , the following probability is negligible

$$\Pr \left[\begin{array}{l} \text{OpenVer}(\text{ck}, c, m_0, o_0) = 1 \\ \wedge \text{OpenVer}(\text{ck}, c, m_1, o_1) = 1 \\ \wedge m_0 \neq m_1 \end{array} \middle| \begin{array}{l} \text{ck} \leftarrow \text{ComGen}(1^\lambda) \\ (c, (m_0, o_0), (m_1, o_1)) \leftarrow \mathcal{A}(\text{ck}) \end{array} \right].$$

Knowledge Binding [BL07]. For every adversary \mathcal{A} that produces a valid commitment c associated to a message that verifies, i.e. such that $\text{ComVer}(\text{ck}, c) = 1$, there is an extractor $\text{Ext}_{\mathcal{A}}$ that is able to output a pre-image m and a valid opening o of c , with overwhelming probability:

$$\Pr \left[\text{OpenVer}(\text{ck}, c, m, o) = 1 \mid \begin{array}{l} \text{ck} \leftarrow \text{ComGen}(1^\lambda) \\ (c; (m, o)) \leftarrow (\mathcal{A} \parallel \text{Ext}_{\mathcal{A}})(\text{ck}) \\ \text{ComVer}(\text{ck}, c) = 1 \end{array} \right] = 1 - \text{negl}(\lambda).$$

For the sake of simplicity, throughout this work, we will omit the commitment key ck from the input of the algorithms, and with a slight abuse of notation, we will adopt the writing $\text{Com}(m) \rightarrow (c, o)$.

2.2 SNARKs – Succinct Non-Interactive Arguments of Knowledge

We recall the definition of (zero-knowledge) succinct non-interactive arguments of knowledge (zk-SNARKs).

Definition 2 (SNARK for NP). A SNARK is defined by three algorithms,

$\Pi.\text{Gen}(1^\lambda, \mathcal{R}) \rightarrow \text{crs}$: on input a security parameter $\lambda \in \mathbb{N}$ and a NP relation \mathcal{R} , the generation algorithm outputs a common reference string crs ;

$\Pi.\text{Prove}(\text{crs}, u, w) \rightarrow \pi$: given a prover reference string crs , an instance u and a witness w s.t. $(u, w) \in \mathcal{R}$, this algorithm produces a proof π ;

$\Pi.\text{Ver}(\text{crs}, u, \pi) \rightarrow b$: on input a verification state crs , an instance u , and a proof π , the verifier algorithm outputs $b = 0$ (reject) or $b = 1$ (accept);

satisfying *completeness*, *succinctness*, *knowledge-soundness* as described below:

Correctness. For all valid statement $(u, w) \in \mathcal{R}$,

$$\Pr \left[\begin{array}{l} \text{Ver}(\text{crs}, u, \pi) = 0 \\ \wedge (u, w) \in \mathcal{R} \end{array} \mid \begin{array}{l} \text{crs} \leftarrow \Pi.\text{Gen}(1^\lambda, \mathcal{R}) \\ \pi \leftarrow \text{Prove}(\text{crs}, u, w) \end{array} \right] = \text{negl}(\lambda);$$

Succinctness. The size of the proof is linear in the security parameter λ , i.e. independent of the size of the computation or the witness;

Knowledge-Soundness [BG93]. A non-interactive proof system Π is *knowledge-sound* for the class \mathcal{Z} of auxiliary input generators if for any PPT adversary \mathcal{A}^{KS} there exists an extractor $\text{Ext}_{\mathcal{A}}$ such that:

$$\Pr \left[\begin{array}{l} \text{Ver}(\text{crs}, u, \pi) = 1 \\ \wedge \mathcal{R}(u, w) = 0 \end{array} \mid \begin{array}{l} \text{crs} \leftarrow \Pi.\text{Gen}(1^\lambda, \mathcal{R}), \text{aux} \leftarrow \mathcal{Z}(\text{crs}) \\ ((u, \pi); w) \leftarrow (\mathcal{A}^{\text{KS}} \parallel \text{Ext}_{\mathcal{A}})(\text{crs}, \text{aux}) \end{array} \right] = \text{negl}(\lambda).$$

Zero Knowledge. A Π protocol is a (statistical) zero-knowledge for a relation \mathcal{R} if there exists a stateful interactive polynomial-size simulator $\text{Sim} = (\text{Sim}^{\text{crs}}, \text{Sim}^{\text{Prove}})$ such that for all stateful interactive distinguishers \mathcal{D} , for every large enough security parameter $\lambda \in \mathbb{N}$, every auxiliary input aux , the two probabilities are negligibly close:

$$\begin{aligned} & \Pr[(u, w) \in \mathcal{R} \wedge \mathcal{D}(\pi) = 1 \mid (\text{crs}) \leftarrow \text{Gen}(1^\lambda), (u, w) \leftarrow \mathcal{D}(\text{crs}, \text{aux}), \\ & \quad \pi \leftarrow \text{Prove}(\text{crs}, u, w)]; \\ & \Pr[(u, w) \in \mathcal{R} \wedge \mathcal{D}(\pi) = 1 \mid (\text{crs}, \text{trap}) \leftarrow \text{Sim}^{\text{crs}}(1^\lambda), (u, w) \leftarrow \mathcal{D}(\text{crs}, \text{aux}), \\ & \quad \pi \leftarrow \text{Sim}^{\text{Prove}}(\text{crs}, \text{trap}, u, \text{aux})]. \end{aligned}$$

Commit and Prove SNARKs. Let $\mathcal{R}(u, w)$ be an NP relation where $w = (\{x_i\}_i, \omega)$. A commit-and-prove SNARK (CaP-SNARK) for commitment scheme \mathcal{Com} and relation $\mathcal{R}(u, w)$ is a SNARK for the “commit-and-prove relation” $\mathcal{R}^{\text{ck}}(u^*, w^*)$ where $u^* = (u, \{c_i\}_i)$, $w^* = (\{x_i\}_i, \{o_i\}_i, \omega)$ and that holds iff $\mathcal{R}(u, (\{x_i\}_i, \omega))$ holds and $\text{OpenVer}(c_i, m_i, o_i) = 1$ for all i . We adopt the syntax for CaP-SNARK used in [CFQ19]:

$\Pi.\text{Gen}(\text{ck}, \mathcal{R}) \rightarrow \text{crs}$: on input a relation-independent commitment key ck and a NP relation \mathcal{R} , it generates the crs ;
 $\Pi.\text{Prove}(\text{crs}, (u, \{c_i\}_i), (\{x_i\}_i, \{o_i\}_i, \omega)) \rightarrow \pi$: outputs a proof;
 $\Pi.\text{Ver}(\text{crs}, (u, \{c_i\}_i), \pi) \rightarrow b$: rejects or accepts the proof.

3 Proof Systems for Arithmetic Function Evaluation over Quotient Polynomial Rings

In this section we describe our commit-and-prove SNARK for arithmetic computations in quotient polynomial rings.

Let \mathbb{R} be the quotient ring $\mathbb{Z}/\langle R(X) \rangle$ for some polynomial $R \in \mathbb{Z}[X]$ of degree d . For a prime $q \gg d$ we define $\mathbb{F} = \mathbb{Z}_q$ a finite field and $\mathbb{R}_q = \mathbb{R}/q\mathbb{R}$. We want to construct a succinct non-interactive zero-knowledge argument system for some relation \mathcal{R}_f of correct evaluation of an arithmetic function $f(\cdot) : \mathbb{R}_q^n \rightarrow \mathbb{R}_q$ taking $n \in \mathbb{N}$ inputs in the quotient ring $\mathbb{R}_q = \mathbb{R}/q\mathbb{R}$. The function f to be evaluated on polynomials $\{P_j\}_{j=1}^n$ in the quotient ring \mathbb{R}_q is considered to be public.

Let $\text{MPoly-Com} = (\text{MPoly.ComGen}, \text{MPoly.Com}, \text{MPoly.ComVer}, \text{MPoly.OpenVer})$ be a linearly homomorphic commitment scheme for (many) univariate polynomials, i.e., the message space M consists in vectors of $n \leq \ell$ polynomials of degree $d \leq \nu$, for some integer bounds ℓ, ν chosen in MPoly.ComGen . In Section 7 we show an efficient instantiation of such a scheme in bilinear groups.

We describe a Commit-and-Prove SNARK, $\text{Rq-}\Pi$, for commitment scheme MPoly-Com and for the following relation

$$\mathcal{R}_f^{\text{ck}} := \{(u = (C, P); w = (\{P_j\}_{j=1}^n, \rho, T)) : \\ \text{MPoly.OpenVer}(C, \{P_j\}, \rho) = 1 \wedge P = f(P_j) - TR\}$$

The relation $\mathcal{R}_f^{\text{ck}}$ implicitly contains two bounds ℓ, ν on, respectively, the number of inputs of f and the degree d_f of f as an arithmetic circuit.

In a nutshell, given a compact commitment C and a public polynomial $P \in \mathbb{R}_q$, our $\text{Rq-}\Pi$ scheme allows to prove that C opens to some polynomials $P_j \in \mathbb{R} \forall j = 1 \dots n$ such that P is the result of evaluating the function f on $\{P_j\}_j$, evaluation done in the polynomial ring \mathbb{R}_q .

High-Level Description of our $\text{Rq-}\Pi$ SNARK. We build our $\text{Rq-}\Pi$ scheme as a combination of the following building blocks:

- $\text{MUniEv-}\Pi = (\text{MUniEv-}\Pi.\text{Gen}, \text{MUniEv-}\Pi.\text{Prove}, \text{MUniEv-}\Pi.\text{Ver})$: a CaP-SNARK for the simultaneous evaluation of n univariate polynomials $\{P_j\}_{j=1}^n$ in a point k , where $\{P_j\}$ are committed with MPoly-Com . Proposing efficient constructions of MPoly-Com and $\text{MUniEv-}\Pi$ are key technical contributions of this paper; these are detailed in Section 7.
- $\text{AC-}\Pi = (\text{AC-}\Pi.\text{Gen}, \text{AC-}\Pi.\text{Prove}, \text{AC-}\Pi.\text{Ver})$: a CaP-SNARK for arithmetic circuits over \mathbb{Z}_q where inputs and outputs are committed (as a vector of degree-0 polynomials) with the MPoly-Com scheme.

Various instantiations of $\text{AC-}\Pi$ compatible with our pairing-based MPoly-Com commitment can be obtained by using for example the compiler recently proposed in [CFQ19];¹ a particularly efficient one is a commit-and-prove variant of [Gro16].

¹ In particular, relevant to our work is the compiler that shows that commit-and-prove SNARKs for Pedersen-like commitments can be made compatible with one another.

The two building blocks above are used as follows.

The prover, knowing a quotient polynomial $T \in \mathbb{Z}_q[X]$ such that $f((P_j)_j) = P + TR$, starts by computing a commitment C_T to $T \in \mathbb{Z}_q[X]$ (which may have degree higher than that of R).

Next, the key idea is that instead of directly proving that $P = f((P_j)_j) - TR$ for the committed polynomials $\{P_j\}$ and T (that would require to work with a large arithmetic circuits f), we use the homomorphic properties of the polynomial ring $\mathbb{Z}_q[X]$ to “compress the computation”. Namely, to prove $P = f((P_j)_j) - TR$, we evaluate all the polynomials in a random point k and then prove the relation on the resulting scalars, using the fact that:

$$\hat{f}(P_j(k)) - R(k)T(k) = (f(P_j) - RT)(k) = P(k).$$

where $\hat{f} : \mathbb{Z}_q^n \rightarrow \mathbb{Z}_q$ is an arithmetic circuit that is the same as f except that every addition (resp. multiplication) in \mathbb{R}_q is replaced by an addition (resp. multiplication) in \mathbb{Z}_q .

This idea is similar to the homomorphic hash function defined by Fiore et al. [FGP14]. In [FGP14], they let this idea work by evaluating the polynomials “in the exponent”, i.e., they publish a set of group elements g^{k^i} , and then they compute homomorphically over these encodings to get $g^{P(k)}$.

This technique however hits two problems: first, they cannot deal with reductions modulo $R(X)$, and second, to compute homomorphically a multiplication on these encodings, they have to “consume” a pairing, and thus only degree-2 computations can be supported.

In our case, we solve these issues by exploiting the power of the commit and prove paradigm in order to obtain, for every evaluation, a fresh random k . Then, having $k \in \mathbb{Z}_q$ allows us to support higher-degree computations as well as to deal with modular reductions.

To proceed with the protocol, the prover thus needs to get a random point k , not of its choice and independent of the values committed in C_T and C and of the statement P . This is possible by using a random oracle **Hash** to obtain a value k on which it evaluates the polynomials $\{P_j(k) = p_j\}_{j=1}^n, R(k) = r, P(k) = p$ and $T(k) = t'$.

Next, the prover compactly commits to the respective evaluations of the polynomials $(T, \{P_j\}_{j=1}^n)$ as (C', ρ') . At this point the prover will use:

1. the **MUniEv- Π** scheme to prove that C' is a commitment to a vector of $n+1$ scalars $(t, \{p_j\}_{j=1}^n)$ that are the results of evaluating in point k a vector of $n+1$ polynomials $(T, \{P_j\}_{j=1}^n)$ that are committed in $C_T \times C$;

Remark 3. We consider linearly homomorphic commitment schemes **MPoly-Com** and we commit in C_T and C to vectors of $n+1 \leq \ell$ polynomials $(C_T, \tau) \leftarrow \text{MPoly.Com}(T, 0, 0 \dots 0)$ and $(C, \rho) \leftarrow \text{MPoly.Com}(0, \{P_j\}_{j=1}^n)$ with an appropriate number of 0's, i.e., $(T, \{P_j\}) = (T, \{0\}) + (0, \{P_j\})$, such that computing $C_T \times C$ results in a commitment $(C_T \times C, \tau + \rho) \leftarrow \text{MPoly.Com}(T, \{P_j\}_{j=1}^n)$ to the concatenation of $T, \{P_j\}$.

2. the **AC- Π** scheme to prove that $p = P(k) = \hat{f}((p_j)_j) - rt'$, and that $t', \{p_j\}_{j=1}^n$ are openings of C' .

More formally, the algorithms of the protocol are described in Figure 1. A detailed intuition of the functionalities of each algorithm follows.

3.1 Formal Description of Our **Rq- Π** Scheme.

We construct a commit-and-prove SNARK scheme **Rq- Π** = (Gen, Prove, Ver) for any relation $\mathcal{R}_f^{\text{ck}}$ with respect to some bounds ℓ, ν on the cardinality of $\{P_j\}_j$ and on the degree d_f of f .

Rq- Π .Gen(ck, $\mathcal{R}_f^{\text{ck}}$) \rightarrow crs

- 1: $\text{crs}_C \leftarrow \text{MUniEv-}\Pi.\text{Gen}(\text{ck}, \mathcal{R}_{\text{eval}})$, $\text{crs}' \leftarrow \text{AC-}\Pi.\text{Gen}(\text{ck}, \hat{\mathcal{R}}_f)$
- 2: return $\text{crs} := (\text{crs}_C, \text{crs}')$

Rq- Π .Prove(crs, x, w)

- 1: $(C, P) := x, (\{P_j\}_{j=1}^n, \rho, T) := w$
- 2: $(C_T, \tau) \leftarrow \text{MPoly.Com}(T)$
- 3: $k \leftarrow \text{Hash}(C, P, C_T)$
- 4: $p = P(k), r = R(k)$,
- 5: $t' = T(k), p_j = P_j(k)$
- 6: $(C', \rho') \leftarrow \text{MPoly.Com}(t', \{p_j\})$
- 7: $u_C := (C_T \times C, C', k)$
- 8: $\pi_C \leftarrow \text{MUniEv-}\Pi.\text{Prove}(\text{crs}_C, u_C, w_C)$,
- 9: $\pi' \leftarrow \text{AC-}\Pi.\text{Prove}(\text{crs}', u', (C', p, r), w')$
- 10: returns $\pi = (C_T, C', \pi_C, \pi')$

Rq- Π .Ver(crs, $x = (C, P), \pi$)

- 1: $\pi := (C_T, C', \pi_C, \pi')$
- 2: $k \leftarrow \text{Hash}(C, P, C_T)$
- 3: $p := P(k), r := R(k)$
- 4: $u_C := (C_T \times C, C', k)$
- 5: $u' := (C', p, r)$
- 6: $b_C \leftarrow \text{MUniEv-}\Pi.\text{Ver}(\text{crs}_C, u_C, \pi_C)$
- 7: $b' \leftarrow \text{AC-}\Pi.\text{Ver}(\text{crs}', u', \pi')$
- 8: return $(b_C \wedge b') = 1$.

Fig. 1. Our SNARK Rq- Π for Evaluations over Polynomial Rings

Relations for MUniEv- Π and AC- Π . We define the intermediate statements $\mathcal{R}_{\text{eval}}, \hat{\mathcal{R}}_f$ to be proven using the two SNARKs, MUniEv- Π and AC- Π :

$\mathcal{R}_{\text{eval}}$: We first define the relation for simultaneous evaluation of multiple polynomials on a point k , to be supported by MUniEv- Π . The prover has to convince the verifier that for a given point k (that in our case is random, but part of the statement) and two commitments $C_T \times C$ and C' , it knows the corresponding opening values $(T, \{P_j\}_j, \tau + \rho)$ and $(t', \{p_j\}_j, \rho')$ such that $P_j(k) = p_j$ for all j , and $T(k) = t'$.

More formally, MUniEv- Π .Prove takes as input a statement $u_C = (C_T \times C, C', k)$, and a witness $w_C = ((T, \{P_j\}), (t', \{p_j\}), \tau + \rho, \rho')$, and $\mathcal{R}_{\text{eval}}$ holds for (u_C, w_C) iff:

$$\begin{aligned} \mathcal{R}_{\text{eval}} := \{ & (u_C, w_C) : \forall j, p_j = P_j(k) \wedge t' = T(k) \wedge (C', \rho') = \text{MPoly.Com}(t', \{p_j\}) \\ & \wedge (C_T \times C, \tau + \rho) = \text{MPoly.Com}(T, \{P_j\}_j) \}. \end{aligned}$$

$\hat{\mathcal{R}}_f$: We define the relation for correct computation of \hat{f} , to be supported by AC- Π . The prover has to convince the verifier that an equality holds for some scalar values $t', \{p_j\}, p, r \in \mathbb{Z}_q$. The inputs p, r are known by the verifier (they are public) and $t', \{p_j\}$ are given implicitly in a committed form $(C', \rho') = \text{MPoly.Com}(t', \{p_j\})$. More formally, given a statement $u' = (C', p, r)$ and a witness $w' = (\rho', t', \{p_j\})$ for the computation $p = \hat{f}(p_j) - rt'$ and for the opening of C' , the relation is defined as follows:

$$\hat{\mathcal{R}}_f := \{(u', w') : p = \hat{f}(p_j) + rt' \wedge (C', \rho') = \text{MPoly.Com}(t', \{p_j\})\}.$$

CRS Generation. The setup algorithm Rq- Π .Gen(ck, $\mathcal{R}_f^{\text{ck}}$), given a commitment key $\text{ck} \leftarrow \text{MPoly.ComGen}(1^\lambda)$ that supports commitments up to ℓ different polynomials $P_j \in \mathbb{R}_q$ (all of degrees $\leq d$) and one commitment to a polynomial $T \in \mathbb{Z}_q[X]$ of higher degree (up to ν)² and the NP relation $\mathcal{R}_f^{\text{ck}}$ including the bound parameters ℓ, ν , outputs a crs enabling the proof and verification of a function f of degree $d_f < \nu$ over a set of polynomials $\{P_j\}_{j=1}^n$ of cardinality $n \leq \ell$.

First it runs the generation algorithm for MUniEv- Π and computes a part of the setup, $\text{crs}_C \leftarrow \text{MUniEv-}\Pi.\text{Gen}(\text{ck}, \mathcal{R}_{\text{eval}})$.

² The commitment key ck can have some special property for optimization, for example, it may consist of two keys, one for committing to polynomials $P_j \in \mathbb{R}_q$ of degrees $\leq d$ and another longer key to commit to polynomials $T \in \mathbb{Z}_q[X]$ of degree ν .

Then it generates a common reference string for AC- Π that will be used for proving computations of $\hat{f}: \text{crs}' \leftarrow \text{AC-}\Pi.\text{Gen}(\text{ck}, \hat{\mathcal{R}}_f)$. As an observation, AC- Π assumes commitments to vectors of scalars; these can be done with MPoly-Com, by seeing them as vectors of degree-0 polynomials.

Prover. Given a reference string crs , statement $u = (C, P)$ and witness $w = (\{P_j\}_{j=1}^n, \rho, T)$ where P is a public polynomial, C is a compact commitment to polynomials $\{P_j\}_{j=1}^n \in \mathbb{R}_q$ with opening ρ , and $T \in \mathbb{Z}_q[X]$ is a quotient polynomial, the prover algorithm produces a proof π that $f((P_j)_j) = P + TR$ as follows:

- The prover commits to $T = \sum_{i=0}^{\nu} T_i X^i: (C_T, \tau) \leftarrow \text{MPoly.Com}(T)$.
- The prover then runs $k \leftarrow \text{Hash}(C, P, C_T)$ to obtain a random value k .
- The prover evaluates the polynomials in $k: \{P_j(k) = p_j\}_{j=1}^n, R(k) = r, P(k) = p$ and $T(k) = t$.
- The prover commits the respective evaluations $t', \{p_j\}_{j=1}^n$ as $(C', \rho') \leftarrow \text{MPoly.Com}(\text{ck}, t', \{p_j\}_{j=1}^n)$.
- The prover runs the algorithm for MUniEv- Π to prove that the opening values $t', \{p_j\}$ of the commitment C' are evaluation in k of the polynomials $T, \{P_j\}$, committed in $C_T \times C$:

$$\pi_C \leftarrow \text{MUniEv-}\Pi.\text{Prove}(\text{crs}_C, u_C, w_C)$$

$$\text{where } u_C = (C_T \times C, C', k), w_C = ((T, \{P_j\}), (t', \{p_j\}), \tau + \rho, \rho').$$

- It then runs the proving algorithm of AC- Π for proving the evaluation of \hat{f} on scalars with a witness w' for the computation $p = \hat{f}(p_j) - rt$ and for the opening of C' :

$$\pi' \leftarrow \text{AC-}\Pi(\text{crs}', u' = (C', p, r), w').$$

- The prover eventually outputs $\pi = (C_T, C', \pi_C, \pi')$.

Verifier. The algorithm Ver on input a statement $u = (C, P)$ and a proof $\pi := (C_T, C', \pi_C, \pi')$ recomputes the randomness k by running $k \leftarrow \text{Hash}(C, P, C_T)$. Then the Verifier has only to evaluate the known polynomials P, R in k obtaining $p := P(k), r := R(k)$. Once it has all the elements to redefine the two statements $u_C := (C_T \times C, C', k)$ and $u' := (C', p, r)$ for the proofs π_C and π' it runs the corresponding verification algorithms of these two SNARKs, MUniEv- Π .Ver and AC- Π .Ver to check the proofs and outputs the conjunction of the two answers.

3.2 Security Analysis

About the above construction, we can state the following security result.

Theorem 4. *Assuming that AC- Π and MUniEv- Π are secure commit-and-prove arguments of knowledge, the new construction Rq- Π described above satisfies completeness, succinctness, zero-knowledge and knowledge-soundness.*

Proof. Before diving in the technicalities of the security proof, we provide a short intuition for the knowledge soundness property. The proof consists of two main steps: First, we rely on the knowledge-soundness of the two SNARKs to show that for any adversary creating an accepting proof there is a knowledge extractor that, with all but negligible probability, returns witnesses that correctly satisfy the two relations $\mathcal{R}_{\text{eval}}, \hat{\mathcal{R}}_f$ mentioned previously. Second, the only remaining possibility is that the polynomial $V = P^* - f(P_j) + TR$ is nonzero. However, $V(k) = 0$ and this holds for a random point k sampled by the random oracle independently of V , which can happen only with probability $\text{deg}(V)/q$ which is negligible.

Correctness. We aim to prove that under the hypothesis that the commitment (C, ρ) on $\{P_j\}_j$ open correctly and the two SNARKs are secure, the previous protocol is correct, proving the evaluation of f on polynomials P_j in the ring \mathbb{R}_q . Correctness of the protocol follows from the

correctness of MUniEv- Π and AC- Π schemes. If the prover follows the protocol as expected, the commitments C_T, C' are correctly computed, the two proofs π_C, π' are generated honestly, then from the correctness of the two SNARK the verification algorithm accepts with overwhelming probability.

Knowledge Extractor. First we build for any PPT adversary \mathcal{A} against the SNARK a knowledge-extractor $\text{Ext}_{\mathcal{A}}$ that runs on the same input as the adversary \mathcal{A} . Moreover, whenever \mathcal{A} outputs $(x = (C, P), \pi)$ where π is a proof that verifies, the extractor $\text{Ext}_{\mathcal{A}}$ produces a corresponding witness $w = (\{P_j\}_{j=1}^n, \rho)$.

To this end, we should show that from any \mathcal{A} we can define two adversaries $\text{M.}\mathcal{A}$ and $\text{P.}\mathcal{A}$ for the MUniEv- Π and AC- Π schemes respectively. These adversaries are simply defined: First, from the input crs, aux of adversary \mathcal{A} , we can redefine their own crs 's and auxiliary information.

$\text{M.}\mathcal{A}$ just takes the crs_C and redefines the remaining elements as aux_C . $\text{P.}\mathcal{A}$ proceeds similarly, partitions the elements in crs as follows: $(\text{crs}', \text{aux}')$. Next, both $\text{M.}\mathcal{A}$ and $\text{P.}\mathcal{A}$ execute \mathcal{A} , get its output $\pi = (C_T, C', \pi_C, \pi')$ and return as respective outputs the subpart π_C and π' of the proof π .

By the knowledge soundness of the two schemes MUniEv- Π and AC- Π we can deduce that there exist respective extractors M.Ext and P.Ext that output the respective witnesses $w_C = (T, \{P_j\}, t', \{p_j\}, \rho, \tau, \rho')$ and w' .

From these two extractors we define $\text{Ext}_{\mathcal{A}}$ by keeping only parts of the witnesses: $w := (\{P_j\}, \rho)$. Finally, by the knowledge soundness of MUniEv- Π and AC- Π schemes, we have that for an accepting proof π_C , respectively π' , the extractors M.Ext and P.Ext return a wrong witness w_C, w' with negligible probability, and consequently, the same holds also for $\text{Ext}_{\mathcal{A}}$.

Remark 5. Notice that we require in the knowledge soundness Theorem 2 the extractor $\text{Ext}_{\mathcal{A}}$ to take the same input as the adversary \mathcal{A} . In our specific case, \mathcal{A} is an adversary with black-box access to a random oracle Hash. We may consider the slightly different knowledge soundness definition for oracle SNARKs (OSNARKs) from [FN16]. Fortunately, in the same work, the authors show a positive result on the existence of such OSNARKs for (pseudo)random oracles, based on classical SNARKs that are assumed to satisfy proof of knowledge with respect to randomly-distributed auxiliary input. This way we can deal with black-box access to Hash, as such hash function can be simulated with a random string as auxiliary input.

Soundness. Above we have basically shown that for every \mathcal{A} there exists an extractor $\text{Ext}_{\mathcal{A}}$ that with all but negligible probability returns a witness such that the two statements are valid. In particular, the knowledge soundness of the MUniEv- Π gives us that the values $t', \{p_i\}$ are correct evaluations in point k of the polynomials $T, \{P_j\}_{j=1}^n$, while the knowledge soundness of CaP - Π gives us that $p^* - \hat{f}(p_j) + t'r = 0$. The only remaining possible case, in which the adversary \mathcal{A} would be successful in cheating is if the polynomial $V = P^* - f(P_j) + TR$ is not zero. However, $p^* - \hat{f}(p_j) + t'r = 0$ means that $V(k) = 0$.

Based on our choice of $q \gg d$ and the random choice of $k \in \mathbb{Z}_q$ we can argue that $\Pr[V(k) = 0] = \text{negl}$.

Indeed, the probability that the random point k generated by the random oracle Hash, after (and thus independently) of the values C, P, C_T , to be a root of the non-zero polynomial V is $\deg(V)/q$ which is negligible, since the degrees of the polynomials are assumed to be bounded by $\text{poly}(\lambda)$. This shows that V must be the zero polynomial.

Zero-Knowledge. We have to construct a simulator $\text{Sim} = (\text{Sim}^{\text{crs}}, \text{Sim}^{\text{Prove}})$ as in the Theorem 2, using the zero-knowledge simulators of the underlying SNARKs: $(\text{Sim}^{\text{crs}_C}, \text{Sim}^{\text{MUniEv-}\Pi.\text{Prove}})$, $(\text{Sim}^{\text{crs}'}, \text{Sim}^{\Pi})$ as follows:

Sim^{crs} is the same as Gen, but for the two specific crs_C and crs' that are generating by running respectively $(\text{crs}_C, \text{trap}_C) \leftarrow \text{Sim}^{\text{crs}_C}(1^\lambda)$ and $(\text{crs}', \text{trap}') \leftarrow \text{Sim}^{\text{crs}'}(1^\lambda)$ for the two zero-knowledge SNARKs.

$\text{Prove}(\text{crs}, x, w)$	$\text{Sim}^{\text{Prove}}(\text{crs}, x)$
1: $(C, P) := x, (\{P_i\}_{i=1}^n, \rho, T) := w$	1: $(C, P) := x$
2: $(C_T, \tau) \leftarrow \text{MPoly.Com}(T)$	2: $(C_0, \tau) \leftarrow \text{MPoly.Com}(0)$
3: $k \leftarrow \text{Hash}(C, P, C_T)$	3: $k \leftarrow \text{Hash}(C, P, C_0)$
4: $p = P(k), r = R(k),$	4: $p = P(k), r = R(k),$
5: $t' = T(k), p_i = P_i(k)$	5: $t^* = 0, p_i^* = 0$
6: $(C', \rho') \leftarrow \text{MPoly.Com}(t', \{p_i\})$	6: $(C^*, \rho') \leftarrow \text{MPoly.Com}(t^*, \{p_i^*\})$
7: $u_C := (C_T, C, C', k)$	7: $u_C := (C_0 \ C, C^*, k)$
8: $\pi_C \leftarrow \text{MUniEv-}\Pi.\text{Prove}(\text{crs}_C, u_C, w_C),$	8: $\pi_C \leftarrow \text{Sim}^{\text{MUniEv-}\Pi.\text{Prove}}(\text{crs}_C, \text{trap}_C, u_C),$
9: $\pi' \leftarrow \text{AC-}\Pi.\text{Prove}(\text{crs}', u' = (C', p, r), w')$	9: $\pi' \leftarrow \text{Sim}^{\Pi}(\text{crs}', \text{trap}', u' = (C^*, p, r))$
10: returns $\pi = (C_T, C', \pi_C, \pi')$	10: returns $\pi = (C_0, C^*, \pi_C, \pi')$

Fig. 2. A Simulator for the Zero-Knowledge.

Then, $\text{Sim}^{\text{Prove}}$ is able to generate a simulated proof for any commitment C and any polynomial $P \in \mathbb{R}_q$ by committing any $T^* \in \mathbb{Z}_q[X]$ (we can use $T^* := 0$) and then using the simulators for the zero-knowledge of the two underlying SNARKs. We proceed with a sequence of games in order to show the indistinguishability of the simulation.

Hybrid 0. This is the real protocol, described in Figure 2, where proof π is generated by Prove algorithm.

Hybrid 1. In this game, we still use the witness of the evaluation, $w = (\{P_i\}_{i=1}^n, \rho)$, and we generate $(C_T, \tau) \leftarrow \text{MPoly.Com}(\text{ck}, T)$ as in step 2 of the real protocol, but in order to generate the proof π , we run instead the zero-knowledge simulators for the two SNARKs, $(\text{Sim}^{\text{crs}_C}, \text{Sim}^{\text{MUniEv-}\Pi.\text{Prove}})$ and $(\text{Sim}^{\text{crs}'}, \text{Sim}^{\Pi})$.

Based on the fact that $\text{MUniEv-}\Pi$ and $\text{AC-}\Pi$ are zero-knowledge schemes, the two games are perfectly indistinguishable.

Hybrid 2. The $\text{Sim}^{\text{Prove}}$ algorithm described in Figure 2 outputs the proof. Based on the perfectly hiding property of the commitment scheme MPoly-Com the values C_0 and C_T as well as C^* and C' in the two hybrids are indistinguishable. □

4 Applications to Computing on Encrypted Data

In this section we detail on how we can use our scheme $\text{Rq-}\Pi$ for computations over polynomial rings to build a VC scheme with input and output privacy.

4.1 Verifiable Computation

Here we recall the notion of *verifiable computation* from [GGP10]. We adapt the definitions to fit the setting (that is in the scope of our construction) where we have public verifiability and public delegatability [PRV12], as well as privacy of the inputs and outputs. A VC scheme $\mathcal{VC} = (\text{KeyGen}, \text{ProbGen}, \text{Compute}, \text{Verify}, \text{Decode})$ consists of the following algorithms:

$\text{KeyGen}(1^\lambda, f) \rightarrow (PK_f, SK_f)$: Given the security parameter, the key generation algorithm outputs a public key and a matching secret key for the function f .

$\text{ProbGen}_{PK_f}(x) \rightarrow (\sigma_x, \tau_x)$: The problem generation algorithm uses the public key PK_f to encode the input x into a public value σ_x , to be given to the computing party, and a public value τ_x to be given to the verifier.

$\text{Compute}_{PK_f}(\sigma_x) \rightarrow \sigma_y$: Given the public key PK_f and the encoded input, the compute algorithm returns an encoded version of the function's output.

$\text{Verify}_{PK_f}(\tau_x, \sigma_y) \rightarrow acc$: Given the public key PK_f for function f , and the public verifier information τ_x , the verification algorithm accepts (output $acc = 1$) or rejects (output $acc = 0$) an output encoding σ_y .

$\text{Decode}_{SK_f}(\sigma_y) \rightarrow y$: Given the secret key SK_f for function f , and an output encoding σ_y , the decoding algorithm outputs a value y .

The correctness of a VC scheme is the obvious property: if one runs **Compute** on an honestly generated input encoding of \mathbf{x} , then the output must verify and its decoding should be $y = f(\mathbf{x})$.

For security, intuitively we want to say that an adversary that receives the public parameters for a function f and an encoding of an input \mathbf{x} cannot create an encoding that passes verification and decodes to $y' \neq f(\mathbf{x})$. More formally, we say that a publicly verifiable computation scheme \mathcal{VC} is *secure* for a function f , if for any PPT adversary \mathcal{A} , we have that $\Pr[\mathbf{Exp}_{\mathcal{A}}^{\text{PubVerif}}[\mathcal{VC}, f, \lambda] = 1] = \text{negl}(\lambda)$, where the experiment $\mathbf{Exp}_{\mathcal{A}}^{\text{PubVerif}}$ is described below.

The *input privacy* notion intuitively says that no information about the inputs is leaked. This is defined using a typical indistinguishability experiment. Note that input privacy implies also *output privacy*. More formally, we say that a publicly verifiable (and publicly delegatable) VC scheme \mathcal{VC} is *private* for a function f , if for any PPT adversary \mathcal{A} , we have that $\Pr[\mathbf{Exp}_{\mathcal{A}}^{\text{Priv}}[\mathcal{VC}, f, \lambda] = 1] \leq \frac{1}{2} + \text{negl}(\lambda)$, where the experiment $\mathbf{Exp}_{\mathcal{A}}^{\text{Priv}}$ is described below.

<p>Experiment $\mathbf{Exp}_{\mathcal{A}}^{\text{PubVerif}}[\mathcal{VC}, f, \lambda]$</p> <p>$(PK, SK) \leftarrow \text{KeyGen}(1^\lambda, f);$</p> <p>$\mathbf{x} \leftarrow \mathcal{A}(PK_f);$</p> <p>$(\sigma_x, \tau_x) \leftarrow \text{ProbGen}_{PK_f}(\mathbf{x});$</p> <p>$\hat{\sigma}_y \leftarrow \mathcal{A}(PK_f, \sigma_x, \tau_x);$</p> <p>$a\hat{c}c \leftarrow \text{Verify}_{PK_f}(\tau_x, \hat{\sigma}_y)$</p> <p>$\hat{y} \leftarrow \text{Decode}_{SK_f}(\hat{\sigma}_y)$</p> <p>If $a\hat{c}c = 1$ and $\hat{y} \neq f(\mathbf{x})$,</p> <p>output ‘1’, else ‘0’;</p>	<p>Experiment $\mathbf{Exp}_{\mathcal{A}}^{\text{Priv}}[\mathcal{VC}, f, \lambda]$</p> <p>$b \leftarrow \{0, 1\};$</p> <p>$(PK_f, SK_f) \leftarrow \text{KeyGen}(1^\lambda, f);$</p> <p>$(\mathbf{x}_0, \mathbf{x}_1) \leftarrow \mathcal{A}(PK_f)$</p> <p>$(\sigma_b, \tau_b) \leftarrow \text{ProbGen}_{PK_f}(\mathbf{x}_b);$</p> <p>$\hat{b} \leftarrow \mathcal{A}(PK_f, \sigma_b)$</p> <p>If $\hat{b} = b$, output ‘1’, else ‘0’</p>
--	--

4.2 Our VC Scheme

We describe our VC scheme below. The construction is essentially an instantiation of the generic solution of Fiore et al. [FGP14] when using an homomorphic encryption scheme whose homomorphic evaluation algorithm fits our relation \mathcal{R}_f . This can be obtained by using HE schemes in the Ring-LWE setting where the ciphertext space works over the same ring \mathbb{R}_q supported by our Rq- Π construction, and where the evaluation algorithm does not involve modulus switches and rounding operations. An example of such a scheme is the one of Brakerski and Vaikunthanatan [BV11].

Let $\text{MPoly-Com} = (\text{MPoly.ComGen}, \text{MPoly.ComVer}, \text{MPoly.OpenVer})$ be a polynomial commitment scheme, $\text{Rq-}\Pi = (\text{Rq-}\Pi.\text{Gen}, \text{Rq-}\Pi.\text{Prove}, \text{Rq-}\Pi.\text{Ver})$ be a CaP zk-SNARK for polynomial rings computation, and let $\text{HE} = (\text{HE.KeyGen}, \text{HE.Enc}, \text{HE.Eval}, \text{HE.Dec})$ be a homomorphic encryption scheme in the Ring-LWE setting. Then our VC scheme works as follows:

$\text{KeyGen}(1^\lambda, \hat{f}) \rightarrow (PK_f, SK_f)$:

- Run $(\text{pk}, \text{sk}) \leftarrow \text{HE.KeyGen}(\lambda)$ to generate a key pair for HE.
- Run $\text{crs} \leftarrow \text{Rq-}\Pi.\text{Gen}(\text{ck}, \mathcal{R}_f^{\text{ck}})$ to generate the common reference string of Rq- Π for the relation $\mathcal{R}_f^{\text{ck}}$.
- Set $PK_f = (\text{pk}, \text{crs}, \hat{f})$ and $SK_f = (\text{sk}, \text{crs})$.

$\text{ProbGen}_{PK_f}(\mathbf{x}) \rightarrow (\sigma_x, \tau_x)$:

- Parse $\mathbf{x} = \{x_i\}_{i=1}^n$ and compute ciphertexts $P_i \leftarrow \text{HE.Enc}(\text{pk}, x_i)$
- Compute the commitment $(C, \rho) = \text{MPoly.Com}(\{P_i\})$ and define $\sigma_x = (C, \{P_i\}, \rho)$ and $\tau_x = C$.

$\text{Compute}_{PK_f}(\sigma_x) \rightarrow \sigma_y$:

- Parse $\sigma_x = (C, \{P_i\}, \rho)$;
- Compute the result ciphertext $P \leftarrow \text{HE.Eval}(\text{pk}, \hat{f}, \{P_i\}) = f(\{P_i\})$.
- Run $\pi \leftarrow \text{Rq-}\Pi.\text{Prove}(\text{crs}, (C, P), (\{P_i\}, \rho))$.
- Define $\sigma_y = (P, \pi)$

$\text{Verify}_{PK_f}(\tau_x, \sigma_y) \rightarrow acc$: output $b \leftarrow \text{Rq-}\Pi.\text{Ver}(\text{crs}, (C, P), \pi)$.
 $\text{Decode}_{SK_f}(\tau_x, \sigma_y) \rightarrow y$: $\text{Decrypt } y = \text{HE.Dec}(\text{sk}, P)$.

Following the general result in [FGP14], the scheme satisfies correctness, security and privacy. In particular, privacy relies on the semantic security of HE, and security on the soundness of the SNARK.

4.3 Preserving Privacy of the Inputs Against the Verifier

The VC scheme described in the previous section works when the homomorphic computation $P \leftarrow f(\{P_i\})$ on the ciphertexts is deterministic. This can raise the issue that the result ciphertext P may reveal information on the plaintexts $\{x_i\}$ underlying $\{P_i\}$ (e.g., in lattice-based schemes such information may be inferred by looking at the distribution of the noise recovered as P 's decryption time).

It would be therefore interesting to capture the setting where one wants to hide information on the x_i 's even from the decryptor. Such a property would turn useful in scenarios where the data encryptor and decryptor are different entities. As an example, consider the case of users that store medical data x on a cloud server which computes some query f on behalf of an analyst, who however is not entitled to learn more than $f(x)$.

In this section, we provide a formal definition of this property, that we call context-hiding, and then describe how our scheme from the previous section can be extended to achieve this additional property.

Defining Context-Hiding. Informally, this property says that output encodings σ_y , as well as the input verification tokens τ_x , do not reveal any information on the input \mathbf{x} . Notably this should hold even against the holders of the secret key SK_f . We formalize this definition in a zero-knowledge style, requiring the existence of simulator algorithms that, without knowing the input, should generate (τ_x, σ_y) that look like the real ones. More precisely, a VC scheme is context-hiding for a function f if there exist simulator algorithms S_1, S_2 such that:

- the keys (PK_f, SK_f) and (PK'_f, SK'_f) are statistically indistinguishable, where $(PK_f, SK_f) \leftarrow \text{KeyGen}(1^\lambda, f)$ and $(PK'_f, SK'_f, \text{td}) \leftarrow S_1(1^\lambda, f)$;
- for any input \mathbf{x} , the following distributions are negligibly close

$$(PK_f, SK_f, \sigma_x, \tau_x, \sigma_y) \approx (PK_f, SK_f, \sigma_x, \tau'_x, \sigma'_y)$$

where $(PK_f, SK_f, \text{td}) \leftarrow S_1(1^\lambda, f)$, $(\sigma_x, \tau_x) \leftarrow \text{ProbGen}_{PK_f}(\mathbf{x})$,
 $\sigma_y \leftarrow \text{Compute}_{PK_f}(\sigma_x)$, and $(\sigma'_y, \tau'_x) \leftarrow S_2(\text{td}, SK_f, f(\mathbf{x}))$.

Our Context-Hiding Secure VC scheme. Before describing the scheme in detail, let us provide some intuition.

The first observation is that for the HE scheme this problem can be solved by adding to the result P an encryption of 0, P_0^* , whose noise can statically hide that in P (a so called noise flooding technique). However if we do this change in our VC scheme we have two issues: (1) the computation is not deterministic anymore; (2) the prover may create a bogus encryption of 0, not of the correct distribution, in order to make decryption fail. We can solve these issues by using the fact that, as underlying tool for verifiability, we are using a SNARK that can handle deterministic computations. In particular, we can do the following.

For (2) we add to the public key s honestly generated encryptions of 0 $\{P_i^*\}_{i=1}^s$, and then ask the untrusted party to compute the result as $P' = P + P_0^*$ with $P_0^* = \sum_{i=1}^n b_i \cdot P_i^*$, for uniformly random bits b_i . By choosing appropriately the noise parameters in the P_i^* 's and by taking $s \approx \lambda$, based on the leftover hash lemma, P_0^* can statistically hide the noise in P .

Formally, adding such a randomization at the end of computing a function f guarantees leveled circuit privacy. In a nutshell, a somewhat-FHE HE is leveled circuit private if there exists a simulator algorithm HE.S such that $\text{HE.S}(\text{pk}, d, f(\mathbf{x})) \approx \text{HE.Eval}(\text{pk}, f, \text{HE.Enc}(\mathbf{x}))$ are

statistically close. Here the input d taken by the simulator represents information on the depth of f .

For (1), we simply consider proving a slightly different relation, that is:

$$\begin{aligned} \mathcal{R}_f^* := & \{(u = (C, P', \{P_i^*\}_{i=1}^s); w = (\{P_j\}_{j=1}^n, T, \rho, b_1, \dots, b_s)) : \\ & (C, \rho) = \text{MPoly.Com}(\{P_j\}) \wedge \forall i \in [s] b_i \in \{0, 1\} \wedge \\ & P' = f(P_j) + \sum_{i=1}^s b_i P_i^* - TR \} \end{aligned}$$

To use our scheme Rq- Π on the above relation, we can do the following. Given a function $f : \mathbb{R}_q^n \rightarrow \mathbb{R}_q$, define the function $f' : \mathbb{R}_q^{n+s} \times \mathbb{Z}_q^s \rightarrow \mathbb{R}_q$ that takes $n + 2s$ inputs such that

$$\hat{f}'(x_1, \dots, x_n, o_1, \dots, o_s, b_1, \dots, b_s) = \hat{f}(x_1, \dots, x_n) + \sum_{i=1}^s b_i \cdot o_i.$$

Then we use our Rq- Π on the following relation

$$\begin{aligned} \mathcal{R}'_f := & \{(u = (C', P'); w = (\{P_j\}_{j=1}^n, \{P_i^*\}_{i=1}^s, \{b_i\}_{i=1}^s, T, \rho')) : \\ & (C', \rho') = \text{MPoly.Com}(\{P_j\}, \{P_i^*\}, \{b_i\}) \wedge \forall i \in [s] b_i \in \{0, 1\} \wedge \\ & P' = f'(P_j, \{P_i^*\}, \{b_i\}) - TR \} \end{aligned}$$

where $C' = C \times C^* \times C_b$ and $\rho' = \rho + \rho^* + \rho_b$. It can be seen that \mathcal{R}'_f matches the format $\mathcal{R}_{f'}$ (for the function f' and a larger set of inputs) of relations supported by our Rq- Π scheme. One change however is that the commitment C' cannot be created directly by ProbGen as it contains elements that depend on a specific computation. We can solve this problem by using the homomorphic property of the commitment scheme: namely we assume that at key generation a commitment $(C^*, \rho^*) = \text{MPoly.Com}(\{P_i^*\})$ is created and made public, and that the prover creates a similar commitment $(C_b, \rho_b) = \text{MPoly.Com}(\{b_i\})$ to the random coefficients. Then C' can be obtained as $C \cdot C^* \cdot C_b$ and its opening is $\rho' = \rho + \rho^* + \rho_b$.

A more precise description of the protocol is given below.

KeyGen($1^\lambda, \hat{f}$) \rightarrow (PK_f, SK_f):

- Run $(pk, sk) \leftarrow \text{HE.KeyGen}(\lambda)$ to generate the key pair for HE.
- Run $\text{crs} \leftarrow \text{Rq-}\Pi.\text{Gen}(\text{ck}, \mathcal{R}_{f'})$ to generate the Rq- Π crs for the relation $\mathcal{R}_{f'}$.
- For $i = 1$ to s : $P_i^* \leftarrow \text{HE.Enc}(pk, 0)$ and compute a commitment $(C^*, \rho^*) = \text{MPoly.Com}(\{P_i^*\})$.
- Set $PK_f = (pk, \{P_i^*\}_{i=1}^s, C^*, \rho^*, \text{crs}, \hat{f})$ and $SK_f = (sk, \text{crs})$.

ProbGen $_{PK_f}(\mathbf{x}) \rightarrow (\sigma_x, \tau_x)$: this is the same as in the previous section.

Compute $_{PK_f}(\sigma_x) \rightarrow \sigma_y$: parsing $\sigma_x = (C, \{P_i\}, \rho)$, do the following:

- Sample $b_1, \dots, b_s \leftarrow \mathbb{Z}_q$ uniformly at random, and compute a commitment $(C_b, \rho_b) = \text{MPoly.Com}(\{b_i\})$ (thinking of each b_i as a degree-0 polynomial).
- Compute the result ciphertext $P' \leftarrow f(\{P_i\}) + \sum_{i=1}^s b_i P_i^*$.
- Run $\pi \leftarrow \text{Rq-}\Pi.\text{Prove}(\text{crs}, (C \times C^* \times C_b, P'), (\{P_i\}, \{P_i^*\}, \{b_i\}, \rho, \rho^*, \rho_b))$.
- Define $\sigma_y = (P', C_b, \pi)$

Verify $_{PK_f}(\tau_x, \sigma_y) \rightarrow acc$: output $b \leftarrow \text{Rq-}\Pi.\text{Ver}(\text{crs}, (C \times C^* \times C_b, P), \pi)$.

Decode $_{SK_f}(\tau_x, \sigma_y) \rightarrow y$: Decrypt $y = \text{HE.Dec}(sk, P')$.

Theorem 6. *If HE is semantically secure and circuit private, and Rq- Π is knowledge sound and zero-knowledge, then the VC described above is correct, secure, private and context-hiding.*

Proof (Sketch). The proof of the result is rather simple. Below we provide a proof sketch. First, notice that based on the correctness of Rq- Π and that of HE, we obtain correctness of our protocol.

The security follows from the knowledge soundness of the SNARK. The only detail to mention is that we also rely on the correctness of the HE scheme in order to make sure that, for honestly generated ciphertexts $\{P_i\}$ of $\{x_i\}$, and $\{P_i^*\}$ for 0, and for binary coefficients $\{b_i\}$, the ciphertext $P' \leftarrow f(\{P_i\}) + \sum_{i=1}^s b_i P_i^*$ decrypts to $\hat{f}(x)$.

Finally, we can prove context-hiding via a simple hybrid argument based on the privacy property of the HE scheme and the zero-knowledge of our SNARK. We define the \mathcal{VC} simulators as follows. S_1 proceeds exactly as **KeyGen** except that it runs the SNARK simulator $(\text{crs}, \text{td}) \leftarrow \text{Sim}^{\text{crs}}(\mathcal{R}_{f'}, \lambda)$ instead of **Gen**, and set its trapdoor to be td . $S_2(\text{td}, SK_f, y)$ first sets $\tau'_x = C$ where C is created as a commitment to some dummy input. Next, it creates C_b as another commitment to a dummy value, and computes P' as an encryption of y using $\text{HE.S}(\text{pk}, d, y)$ (where d is information on the depth of f), and finally it invokes the SNARK simulator $\pi \leftarrow \text{Sim}^{\text{Prove}}(\text{crs}, (C \times C^* \times C_b, P'))$. Then S_2 outputs τ'_x and $\sigma'_y = (P', C_b, \pi)$.

The indistinguishability of the keys is immediate from the zero-knowledge of the SNARK. For the second property, we can define an hybrid simulator S' that, with knowledge of σ_x , runs as S_2 but creates P' as in **Compute**. It is easy to see that the output of S' is indistinguishable from that of S_2 by the property of **HE.Hide**, also by the hiding of the commitment and by the zero-knowledge of the SNARK we obtain that the values (τ'_x, σ'_y) generated by S' are indistinguishable from the ones generated using **ProbGen** and **Compute**.

5 Bivariate Polynomial Commitment

Our final goal is to build an efficient instantiation of the $\text{MUniEv-}\Pi$ scheme for the evaluation on the same point of *many* univariate polynomials committed with MPoly-Com . This is the key tool for our $\text{Rq-}\Pi$ scheme for computations over polynomial rings presented in Section 3.

We construct MPoly-Com and $\text{MUniEv-}\Pi$ starting from a commitment scheme BivPoly-Com for bivariate polynomials and a commit-and-prove argument $\text{BivPE-}\Pi$ for the partial evaluation, in one variable, of a committed bivariate polynomial.

In this section we recall bilinear pairings and the computational assumptions needed by our schemes, and then we present the BivPoly-Com commitment scheme. The construction of the $\text{BivPE-}\Pi$ commit-and-prove SNARK is described in Section 6, while their conversion into MPoly-Com and $\text{MUniEv-}\Pi$ appears in Section 7.

5.1 Computational Assumptions

Security of our constructions rely on various computational assumptions. We state here our assumptions over bilinear groups. Some of them are standard q-type assumptions in the frame of DLog-hard groups and others are extractable (non-falsifiable) assumptions, a class of assumptions inherent to the security of SNARKs as shown in [GW11].

Bilinear Groups. Let the generator \mathcal{G} input a security parameter λ and output a description of a bilinear group $\text{gk} := (q, \mathbb{G}, \mathbb{G}, \mathbb{G}_T, \mathbf{e}) \leftarrow \mathcal{G}(1^\lambda)$ such that

- q is a λ -bit prime;
- $\mathbb{G}, \mathbb{G}, \mathbb{G}_T$ are cyclic groups of order q ;
- $\mathbf{e} : \mathbb{G} \times \mathbb{G} \rightarrow \mathbb{G}_T$ is a bilinear asymmetric map (pairing), which means that $\forall a, b \in \mathbb{Z}_q : \mathbf{e}(g^a, \mathbf{g}^b) = \mathbf{e}(g, \mathbf{g})^{ab}$;
- if g and \mathbf{g} generate \mathbb{G} and \mathbb{G} respectively, then $\mathbf{e}(g, \mathbf{g})$ generates \mathbb{G}_T ;
- membership in $\mathbb{G}, \mathbb{G}, \mathbb{G}_T$ can be efficiently decided, group operations and the pairing \mathbf{e} are efficiently computable, generators are efficiently sampleable, and the descriptions of the groups and group elements each have size $O(\lambda)$ bits.

The d -Strong Diffie-Hellman Assumption (d -SDH). The Strong Diffie-Hellman assumption [BB08] says that given (g, g^s, \dots, g^{s^d}) it is infeasible to compute $y = g^{\frac{1}{s-r}}$ for a chosen $r \in \mathbb{Z}_q$. In our applications, a few more group elements Σ are given as input to the adversary:

Assumption 1 (d -SDH) *The d -Strong Diffie-Hellman assumption holds relative to a bilinear group \mathbf{gk} if for all PPT adversaries \mathcal{A} we have, on the probability space $\mathbf{gk} \leftarrow \mathcal{G}(1^\lambda)$, $\Sigma \leftarrow ((g, g^s, \dots, g^{s^d}); (\mathbf{g}, \mathbf{g}^s))$, $g \leftarrow_{\$} \mathbb{G}$, $\mathbf{g} \leftarrow_{\$} \mathfrak{G}$, and $s \leftarrow_{\$} \mathbb{Z}_q$:*

$$\text{Adv}_{\mathcal{A}}^{d\text{-sdh}}(\lambda) := \Pr \left[(r, y) \leftarrow \mathcal{A}(\mathbf{gk}, \Sigma) \wedge y = g^{\frac{1}{s-r}} \right] = \text{negl}(\lambda).$$

An adaptation of the proof in Boneh and Boyen [BB08] shows that our variant of the d -SDH assumption holds in the generic bilinear group model.

Knowledge of Exponent Assumptions. The knowledge of exponent (KEA) assumption introduced by Damgard [Dam92] says that given g, g^α in a group \mathbb{G} it is infeasible to create c, \hat{c} so $\hat{c} = c^\alpha$ without knowing a so $c = g^a$ and $\hat{c} = (g^\alpha)^a$.

d -Power Knowledge of Exponent Assumption (d -PKE) is another long-standing extractable assumption. It says that given $\{g, g^s, g^{s^2}, \dots, g^{s^d}, \hat{g}, \hat{g}^s, \hat{g}^{s^2}, \dots, \hat{g}^{s^d}\}$ with $\hat{g} = g^\alpha$, it is infeasible to create c, \hat{c} where $\hat{c} = c^\alpha$ without knowing a_0, a_1, \dots, a_d that satisfy $c = \prod_{i=0}^d (g^{s^i})^{a_i}$.

The (d, ℓ) -Bivariate PKE Assumption ((d, ℓ) -BPKE). We introduce a bivariate power knowledge of exponent assumption that is a simple extension of the popular d -PKE assumption.

The (d, ℓ) -Bivariate Power Knowledge of Exponent Assumption for a bilinear group \mathbf{gk} , noted by (d, ℓ) -BPKE is a hybrid between PKE assumption for d different powers of s and ℓ powers of t and KEA assumption for input $(h, \hat{h} := h^\alpha) \in \mathbb{G}^2$. It takes the two basis $(g, \hat{g} := g^\alpha), (h, \hat{h} := h^\alpha)$ and all the powers $\{g^{s^i t^j}, \hat{g}^{s^i t^j}\}_{i,j=0}^{d,\ell}$ and claims that it is infeasible to create c, \hat{c} such that $\hat{c} = c^\alpha$ without knowing $\delta, \{a_{ij}\}_{i,j=0}^{d,\ell}$, that satisfy $c = h^\delta \prod_{i,j=0}^{d,\ell} (g^{s^i t^j})^{a_{ij}}$. More formally:

Assumption 2 ((d, ℓ) -BPKE) *The (d, ℓ) -BPKE assumption holds relative to a bilinear group \mathbf{gk} for the class \mathcal{Z} of auxiliary input generators if, for every $\text{aux} \in \mathcal{Z}$ and PPT adversary \mathcal{A} , there exists a PPT extractor Ext such that, on the probability space $\mathbf{gk} \leftarrow \mathcal{G}(1^\lambda)$, $\Sigma \leftarrow (g, \{g^{s^i t^j}\}_{i,j=0}^{d,\ell}, \{\hat{g}^{s^i t^j}\}_{i,j=0}^{d,\ell}; (h, \hat{h}, h^s); (\mathbf{g}, \hat{\mathbf{g}}, \mathbf{g}^s))$, $\text{aux} \leftarrow \mathcal{Z}(\mathbf{gk}, \Sigma)$, $g, h \leftarrow_{\$} \mathbb{G}$, $\mathbf{g} \leftarrow_{\$} \mathfrak{G}$, $\alpha, s, t \leftarrow_{\$} \mathbb{Z}_q$, $\hat{g} := g^\alpha$, $\hat{h} := h^\alpha$, and $\hat{\mathbf{g}} := \mathbf{g}^\alpha$:*

$$\text{Adv}_{\mathcal{A}}^{d\text{-pke}}(\lambda) := \Pr \left[\begin{array}{l} (c, \hat{c}; \delta, \{a_{ij}\}_{i,j=0}^{d,\ell}) \leftarrow (\mathcal{A} \parallel \text{Ext})(\mathbf{gk}, \Sigma; \text{aux}) \\ \mathbf{e}(\hat{c}, \mathbf{g}) = \mathbf{e}(c, \mathbf{g}^\alpha) \wedge c \neq h^\delta \prod_{i,j=0}^{d,\ell} (g^{s^i t^j})^{a_{ij}} \end{array} \right] = \text{negl}(\lambda).$$

5.2 Knowledge Commitment for Bivariate Polynomials

Based on an efficient construction of a polynomial commitment scheme proposed by [KZG10] we further construct a knowledge commitment scheme for bivariate polynomials that is perfectly hiding and computationally binding. This will later allow us to use commitments in a CaP-SNARK BivPE- Π for polynomial partial evaluation.

The commitment scheme $\text{BivPoly.Com} = (\text{Biv.ComGen}, \text{Biv.Com}, \text{Biv.ComVer}, \text{Biv.OpenVer})$ consists of four algorithms as described in Figure 3 and it is specialized for (bivariate) polynomials $P \in \mathbb{Z}_q[X, Y]$: the message space M_{ck} is defined by polynomials in $\mathbb{Z}_q[X, Y]$ of degree in X bounded by a value d and degree in Y bounded by some value ℓ .

Remark 7. The Biv.ComGen algorithm computes two extra values $\mathbf{g}_1 := \mathbf{g}^s, h_1 := h^s$ to be added to ck (step 4). Although these elements are not used by the commitment scheme, they are useful to construct our Commit and Prove SNARK for partial evaluations of polynomials committed with BivPoly.Com . In other words, used as a stand alone commitment scheme, BivPoly.Com may have a slightly shorter commitment key ck (by removing step 4 from Biv.ComGen).

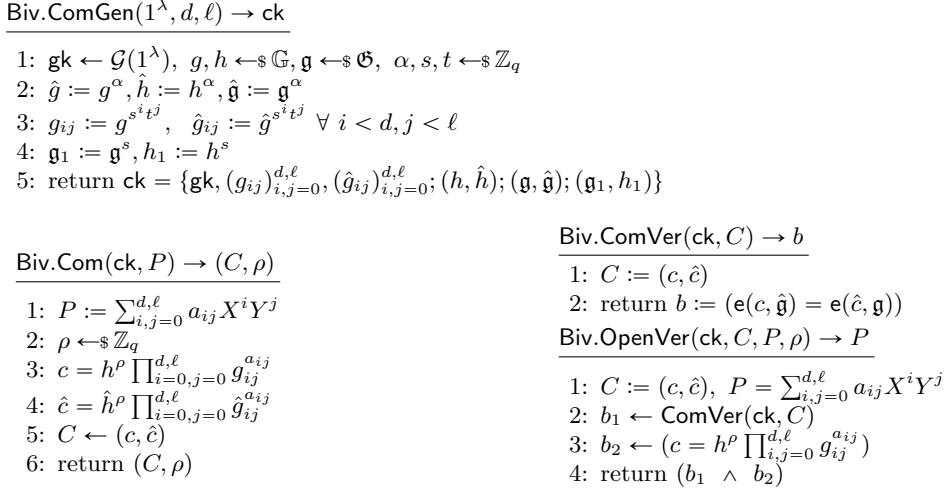

Fig. 3. Our *BivPoly.Com* for Bivariate Polynomial

Security of the Commitment *BivPoly.Com*. We call *BivPoly.Com* a knowledge commitment, since the prover cannot make a valid commitment without “knowing” the committed values. We will rely on the (d, ℓ) – BPKE assumption for extracting the committed polynomials. We can state the following theorem on the security of *BivPoly.Com*:

Theorem 8. *The commitment scheme *BivPoly.Com* is perfectly hiding and computationally binding assuming the d – SDH assumption holds in \mathbb{G} . Moreover, assuming (d, ℓ) – BPKE, the scheme is knowledge binding.*

Proof. We thus prove the required properties:

Perfect Hiding: Since $C = (c, \hat{c}) = (g^\delta, \hat{g}^\delta)$ in \mathbb{G}^2 for some $\delta \in \mathbb{Z}_q$, we have that c and \hat{c} are uniformly distributed elements of \mathbb{G}^2 with the property $\hat{c} = c^\alpha$, independently of the committed values a_i .

Computational Binding: Assume that there exists a non-uniform probabilistic time adversary \mathcal{A} that creates two valid openings $(A = \sum_{i,j=0}^{d,\ell} a_{ij} X^i Y^j, \rho)$ and $(B = \sum_{i,j=0}^{d,\ell} b_{ij} X^i Y^j, \tau)$ of the same commitment $C = (c, \hat{c})$, i.e.,

$$h^\rho g^{A(s,t)} = h^\tau g^{B(s,t)}.$$

By the homomorphic property of the commitment scheme we have $z(\rho - \tau) + A(s, t) - B(s, t) = 0 \pmod q$, for some z such that $h = g^z$. We distinguish the following cases, with specific non-zero polynomials for which s or t are roots:

1. Either the two randomness are the same $\rho - \tau = 0$, leading to $A(s, t) - B(s, t) = 0$. We reduce the case to the d – SDH assumption for s or the ℓ – SDH assumption for t in the following two sub-cases:
 - (a) If $\sum_i (\sum_j (a_{ij} - b_{ij}) t^j) X^i$ is the zero polynomial, meaning that all the coefficients $\sum_j (a_{ij} - b_{ij}) t^j$ are zero $\forall i \in \{0, \dots, d\}$. Since polynomials A and B are different, there exist a $\tilde{i} \in \{0, \dots, d\}$ so that t is a root of the polynomial $\sum_j (a_{\tilde{i}j} - b_{\tilde{i}j}) Y^j$.
 - (b) If there exists at least one index i_0 , such that $\sum_j (a_{i_0j} - b_{i_0j}) t^j \neq 0$, then we have that s is a root of the polynomial defined by fixing t : $\sum_i (\sum_j (a_{ij} - b_{ij}) t^j) X^i$.
2. The two randomness $\rho \neq \tau$, then we construct an algorithm that breaks the **DLog** instance $(g, h = g^z)$.

We now conclude that with non-zero polynomials such that s or t is a root we break the d – SDH assumption for s or the ℓ – SDH assumption for t , and then we explain how we break discrete logarithm in the latter case:

1. We will study separately the two sub-cases, one reduction to $d - \text{SDH}$ assumption for s , and another one for $\ell - \text{SDH}$ assumption for t .

- (a) Consider an adversary \mathcal{A} against the commitment scheme that breaks the binding with non-negligible probability ε . The probability of \mathcal{A} producing a pair A, B satisfying the first case, sub-case (a) is at least $\varepsilon/4$. We show how to construct an algorithm $\mathcal{B}_1^{\text{SDH}}$ against $\ell - \text{SDH}$ assumption for t that calls the adversary \mathcal{A} . The adversary $\mathcal{B}_1^{\text{SDH}}$ using its challenge

$$\sigma = (g, g^s, \dots, g^{s^d}, (\mathfrak{g}, \mathfrak{g}^s))$$

picks random scalars $\alpha, t \leftarrow_s \mathbb{Z}_q$ and computes a commitment key ck for \mathcal{A} :

$$\text{ck} = \{\mathfrak{gk}, (g_{ij})_{i,j=0}^{d,\ell}, (\hat{g}_{ij})_{i,j=0}^{d,\ell}; (h, \hat{h}); (\mathfrak{g}, \hat{\mathfrak{g}})\}.$$

Consider that \mathcal{A} outputs $C = (c, \hat{c})$, two scalars $\rho = \tau$ and two polynomials A and B that both pairs (ρ, A) and (τ, B) are valid openings.

This means we have that $A(s, t) - B(s, t)$ seen as a polynomial in s, t equals to 0. Knowing that for some index \tilde{i} , we have $\sum_j (a_{\tilde{i}j} - b_{\tilde{i}j})t^j = 0$, the adversary $\mathcal{B}_1^{\text{SDH}}$ is able to compute $g^{\frac{1}{\tilde{i}}}$ in the following way: Consider $c_{j_0} = a_{\tilde{i}j_0} - b_{\tilde{i}j_0}$ the first non-zero coefficient of the

polynomial $\sum_j (a_{\tilde{i}j} - b_{\tilde{i}j})Y^j$. We have that $g^{c_{j_0}t^{j_0}} = g^{-t^{j_0}Q(t)}$, so $g^{\frac{1}{\tilde{i}}} = g^{-\frac{Q(t)}{c_{j_0}}}$ for some polynomial $Q(Y)$ of degree $< \ell - c_{j_0}$. $\mathcal{B}_1^{\text{SDH}}$ is then able to solve the $d - \text{SDH}$ instance.

- (b) For the second case, the adversary $\mathcal{B}_2^{\text{SDH}}$ against $d - \text{SDH}$ assumption for s runs an adversary \mathcal{A} that outputs a second-type (b) forgery. In the same manner, the adversary $\mathcal{B}_2^{\text{SDH}}$ using its challenge picks random scalars $\alpha, t \leftarrow_s \mathbb{Z}_q$ and computes a commitment key ck for \mathcal{A} .

We show how to construct an algorithm $\mathcal{B}_2^{\text{SDH}}$ against $d - \text{SDH}$ assumption for s that calls the adversary \mathcal{A} . The adversary $\mathcal{B}_2^{\text{SDH}}$ using its challenge

$$\sigma = (g, g^s, \dots, g^{s^d}, (\mathfrak{g}, \mathfrak{g}^s))$$

picks random scalars $\alpha, t \leftarrow_s \mathbb{Z}_q$ and computes a commitment key ck for \mathcal{A} :

$$\text{ck} = \{\mathfrak{gk}, (g_{ij})_{i,j=0}^{d,\ell}, (\hat{g}_{ij})_{i,j=0}^{d,\ell}; (h, \hat{h}); (\mathfrak{g}, \hat{\mathfrak{g}})\}.$$

In a similar way as in the previous case, with the non-zero polynomial for which s is a root, $\mathcal{B}_2^{\text{SDH}}$ is able to compute $g^{1/s}$ and solve the $d - \text{SDH}$ instance.

2. For this case we construct an algorithm \mathcal{B} that uses \mathcal{A} to efficiently solve a DLog instance. Given a DLog instance $(g, h = g^z)$, the algorithm \mathcal{B} chooses $\alpha, s, t \leftarrow_s \mathbb{Z}_q$, sets $\hat{g} := g^\alpha, \hat{h} := h^\alpha$ and presents

$$\text{ck} = \{\mathfrak{gk}, (g_{ij})_{i,j=0}^{d,\ell}, (\hat{g}_{ij})_{i,j=0}^{d,\ell}; (h, \hat{h}); (\mathfrak{g}, \hat{\mathfrak{g}})\}.$$

to \mathcal{A} .

Since this ck has the same distribution as a real common reference string there is a overwhelming probability for adversary \mathcal{A} to return two valid openings for the same commitment C .

Consider that \mathcal{A} outputs $C = (c, \hat{c})$, two scalars ρ, τ and two polynomials A and B that both pairs are valid openings.

Therefore, we have that $g^{z(\rho-\tau)+A(s,t)-B(s,t)} = 1$ which implies $z(\rho-\tau) + A(s, t) - B(s, t) = 0$. \mathcal{B} is then able to compute the discrete logarithm value $z = \frac{B(s,t)-A(s,t)}{\rho-\tau}$. It is easy to see that the success probability of \mathcal{B} solving the DLog instance is a small constant inferior to the advantage of \mathcal{A} in breaking the binding property of the commitment scheme.

Knowledge Commitment: The existence of a non-uniform probabilistic polynomial time knowledge extractor Ext that extract the contents of the knowledge commitment made by a non-uniform probabilistic polynomial time committer \mathcal{A} that outputs a valid pair (c, \hat{c}) follows directly from the $(d, \ell) - \text{BPKE}$ assumption.

$$\underline{\text{BivPE-}\Pi.\text{Gen}(\text{ck}, \mathcal{R}_{\text{ck}}) \rightarrow \text{crs} := \text{ck}}$$

<u>BivPE-Π.Prove(crs, u, w)</u>	<u>BivPE-Π.Ver(crs, u, π) \rightarrow b</u>

Fig. 4. Our CaP-SNARK for Bivariate Polynomial Partial Evaluation

6 CaP-SNARK for Bivariate Polynomial Evaluation

In this section we show how to construct a commit-and-prove SNARK BivPE- Π for the partial evaluation in a single variable of bivariate polynomials.

6.1 Relations for Bivariate Polynomial Partial Evaluation

The relation \mathcal{R} for partial evaluation of bivariate polynomials is defined over tuples $(k, P(X, Y), Q(Y)) \in \mathbb{Z}_q \times \mathbb{Z}_q[X, Y] \times \mathbb{Z}_q[Y]$ as follows

$$\mathcal{R} := \{(k, P(X, Y), Q(Y)) : Q(Y) = P(k, Y)\}.$$

The scheme we propose in this section is a Commit-and-Prove (CaP) SNARK for the above \mathcal{R} where $P \in \mathbb{Z}_q[X, Y]$ and $Q \in \mathbb{Z}_q[Y]$ are committed in C and C' respectively using BivPoly.Com .³

Namely, following the definition from Section 2.2, BivPE- Π is a zk-SNARK for the following commit-and-prove relation

$$\begin{aligned} \mathcal{R}_{\text{ck}} := \{ & (u = (C, C', k); w = (P, Q, \rho, \rho')) : \\ & (C, \rho) = \text{Biv.Com}(P) \wedge (C', \rho') = \text{Biv.Com}(Q) \wedge Q(Y) = P(k, Y)\}. \end{aligned} \quad (1)$$

6.2 Our BivPE- Π Scheme for Bivariate Polynomial Evaluation

We aim to build an efficient commit-and-prove SNARK, BivPE- Π , dedicated to partial evaluation for bivariate polynomials $P \in \mathbb{Z}_q[X, Y]$ in $X = k \in \mathbb{Z}_q$.

Our scheme is based on an algebraic property of polynomials. We remark that $(X - k)$ perfectly divides the polynomial $P(X, Y) - P(k, Y)$ for $k \in \mathbb{Z}_q$.

BivPE- Π works for an (\mathcal{R} -independent) bivariate polynomial commitment scheme $\text{BivPoly.Com} = (\text{Biv.ComGen}, \text{Biv.Com}, \text{Biv.ComVer}, \text{Biv.OpenVer})$, as detailed in Figure 4, and has to satisfy *completeness*, *succinctness*, *zero-knowledge* and *knowledge-soundness*.

Description of Our BivPE- Π Protocol. Let BivPoly.Com be a bi-variate polynomial knowledge commitment scheme. We construct a zero-knowledge SNARK scheme for any relation \mathcal{R}_{ck} with respect to some bounds d, ℓ on the degrees in X and in Y of the polynomials $P \in \mathbb{Z}_q[X, Y]$ supported by BivPoly.Com . Our protocol is formally depicted in Figure 4.

CRS generation. The setup algorithm outputs a crs enabling the proof and verification of statements for the associated relation \mathcal{R}_{ck} defined in Eq. (1).

We remark that Gen algorithm is just using the same public information (commitment key) ck from the BivPoly.Com scheme.

³ Note that, although Q is a uni-variate polynomial in Y , it can also be seen as a bivariate polynomial.

Prover. Given crs , the statement $u = (C, C', k)$ (two commitments C, C' and an evaluation point k) and the witness $w = (P, Q, \rho, \rho')$ (the corresponding polynomials $P \in \mathbb{Z}_q[X, Y], Q \in \mathbb{Z}_q[Y]$ and their randomness ρ, ρ'), the prover proceeds to compute a proof π that $P(k, Y) = Q(Y)$, $(C, \rho) = \text{Biv.Com}(P)$, and $(C', \rho') = \text{Biv.Com}(Q)$ in two steps:

Step 1. (From 1 to 3 in the Prove algorithm from Figure 4.) The prover computes a witness to the correct (partial) evaluation in $k \in \mathbb{Z}_q$ of the polynomial $P \in \mathbb{Z}_q[X, Y]$ as $P(k, Y) = Q \in \mathbb{Z}_q[Y]$. The witness of this evaluation is a polynomial $W \in \mathbb{Z}_q[X, Y]$ defined as the quotient $W := \frac{P(X, Y) - Q(Y)}{X - k}$. This is a well-defined polynomial in $\mathbb{Z}_q[X, Y]$ if and only if $P(k, Y) = Q \in \mathbb{Z}_q[Y]$. The element of the proof π that enables checking this algebraic property over the polynomials P and Q will be a commitment $(D = (d, \hat{d}), \omega)$ to the polynomial W , where $\omega \leftarrow_s \mathbb{Z}_q$ is a fresh randomness.

Remark 9. To this point, the verifier should be convinced that the polynomial Q is the good evaluation in k of P , only by checking the corresponding polynomial equation evaluated in a random hidden point $(s, t) : W(s, t)(s - k) = P(k, t) - Q(t)$. This can be translated in terms of commitments $(C, \rho)(C', \rho'), (D, \omega)$ to P, Q, W as a pairing check: $e(d, \mathbf{g}_1/\mathbf{g}^k) \cdot e(c/c', \mathbf{g})^{-1} = e(h^{(s-t)\omega - (\rho - \rho')}, \mathbf{g})$ where $C = (c, \hat{c}), C' = (c', \hat{c}'), D = (d, \hat{d})$.

Because of the hiding property, the verifier does not have access to the openings of the commitments, as it does not know the randomness ρ, ρ', ω .

We therefore need the prover to provide something more together with the commitment D . The prover needs to compute an extra proof of knowledge of the randomnesses ω used to create this commitment and of the correct relation to satisfy with respect to the randomness ρ, ρ' of the statement commitments C, C' such that the pairing expression cancels the respective terms $h^{(\rho - \rho')}$ and $h^{(s-t)\omega}$.

This is easily solved by building a Schnorr proof of knowledge of the exponents $\omega, (\rho' - \rho)$ that appear in $\mathbb{A} = e(h^{(s-k)\omega - (\rho - \rho')}, \mathbf{g}) = e(h^{(\rho' - \rho)}h^{(s-k)\omega}, \mathbf{g})$. If we define $\tilde{g} := h_1/h^k = h^{s-k}$, then this proof is a classical Schnorr proof for the public value $\mathbb{A} = e(h^{\rho' - \rho}\tilde{g}^\omega, \mathbf{g}) = e(h, \mathbf{g})^{\rho' - \rho} \cdot e(\tilde{g}, \mathbf{g})^\omega$ in the target group \mathfrak{G} . But we will show we can make it more efficient.

Step 2. (From 4 to 7 in the Prove algorithm from Figure 4.) This step consists in this non-interactive Schnorr proof associated to the value $\mathbb{A} = e(h^{\rho' - \rho}\tilde{g}^\omega, \mathbf{g})$:

- Choose $x, y \in \mathbb{Z}_q$,
- Define $\mathbb{U} = e(h^x\tilde{g}^y, \mathbf{g})$, this corresponds to the first round in the interactive Schnorr proof protocol, where the prover sends its commitment.
- Sample the challenge to the Schnorr proof by running the random oracle (hash function) on input the statement to be proven and the commitment \mathbb{U} : $e \leftarrow \text{Hash}(u, D, \mathbb{U})$,
- Compute the answers $\sigma = x - (\rho' - \rho)e \bmod q$ and $\tau = y - \omega e \bmod q$.

The values sent as Schnorr proof are three scalars e, σ, τ , where e is the output of the hash function $\text{Hash}(u, D, \mathbb{U})$ and does not depend on the size of $\mathbb{U} \in \mathfrak{G}_T$. After the two described steps, the prover algorithm outputs $\pi := (D, e, \sigma, \tau)$.

Verifier. First, the verifier parses the received statement and proof (steps 1 and 2 in the Ver algorithm from Figure 4), then it makes sure the commitments C, C', D are well-formed (steps 3 to 5 in the Ver algorithm from Figure 4) by running the Biv.ComVer algorithm. If this is not the case, we discard the proof π . To verify the proof π , one needs the polynomial equation $W(X, Y)(X - k) = P(k, Y) - Q(Y)$ to hold for some secret evaluation points (s, t) . We can rewrite this equation in terms of pairings applied to the commitments (C, C', D) : $e(d, \mathbf{g}_1/\mathbf{g}^k) \cdot e(c/c', \mathbf{g})^{-1}$. If the polynomials W, P, Q evaluated in the secret points s, t satisfy the equation $W(s, t)(s - k) = P(k, t) - Q(t)$, then all the exponents in base g cancel out in the pairing expression. It is not the case for the exponents in base h which correspond to the randomness used in the commitments. The important remark is that if D is correct, the remaining value

$\mathbb{A} = \mathbf{e}(d, \mathbf{g}_1/\mathbf{g}^k) \cdot \mathbf{e}(c/c', \mathbf{g})^{-1}$ can be written only in terms of the 3 randomness ρ, ρ', ω used to commit to P, Q, W :

$$\mathbb{A} = \mathbf{e}(h^{(s-k)\omega} h^{(\rho'-\rho)}, \mathbf{g}) = \mathbf{e}(h^{\rho'-\rho} \tilde{g}^\omega, \mathbf{g}).$$

This can be checked by the usual verification procedure of the Schnorr proof transmitted in π , *i.e.* the values (e, σ, τ) : Compute $\mathbb{A} = \mathbf{e}(d, \mathbf{g}_1/\mathbf{g}^k) \cdot \mathbf{e}(c/c', \mathbf{g})^{-1}$ and $\mathbb{U} = \mathbf{e}(h^\sigma \tilde{g}^\tau, \mathbf{g}) \cdot \mathbb{A}^e$ then run the Hash function to check whether $e = \text{Hash}(u, D, \mathbb{U})$.

Security of BivPE- Π . The security of our scheme is captured in the following theorem whose proof is elaborated in Section 8:

Theorem 10. *Assuming both the d – SDH and (d, ℓ) – BPKE assumptions hold in the bilinear group \mathbf{gk} , the protocol CaP-BivPE- Π is a zero-knowledge Succinct Non-Interactive Argument of Knowledge in the random oracle model.*

Random Oracle Model. We point out that in the case one is *not* interested in hiding the committed bivariate polynomial P and its partial evaluation Q , then it is possible to define a simplified version of our scheme that does not need the Schnorr-style proof and thus is secure *without* random oracles. This protocol is the same as CaP-BivPE- Π except that one would set $\omega = \rho = \rho' = 0$ (so the commitments are no longer hiding); this way the evaluation proof can be just the commitment D and it can be verified with the pairing check $\mathbf{e}(d, \mathbf{g}_1/\mathbf{g}^k) = \mathbf{e}(c/c', \mathbf{g})$.

7 CaP-SNARK for Simultaneous Evaluations

In this section we show how we can use our BivPE- Π scheme for the partial evaluation of *one* bivariate polynomial on a point k in order to prove the evaluation of *many* univariate polynomials on the same point k . The resulting scheme MUniEv- Π can be used in the protocol presented in Section 4 for verifiable computation using HE on Ring-LWE.

More precisely, we show how to use our BivPoly.Com and BivPE- Π to define a commitment scheme and a compact proof system dedicated to multi-polynomials evaluation in the same random point k : given a single compact knowledge commitment C for a set of univariate polynomials $\{P_j(X)\}_j \in \mathbb{Z}_q[X]$ and a public evaluation point $k \in \mathbb{Z}_q$, we want to prove that some values $\{p_j\}_j$ committed in C' are indeed evaluations of the committed polynomials in this point k .

7.1 Commitment for Multiple Univariate Polynomials

We describe below, MPoly-Com, our new knowledge commitment for a set of univariate polynomials. It is obtained in a straightforward way from BivPoly.Com. It is defined as follows, where for simplicity we consider $\ell + 1$ committed univariate polynomials $P_j = \sum_{i=0}^d p_{ij} X^i$ for all $0 \leq j \leq \ell, 0 \leq i \leq d$:

MPoly.ComGen($1^\lambda, d, \ell$) \rightarrow ck: Given some degree bound d and some maximal bound $\ell + 1$ on the cardinal of the polynomial set to be committed, it runs $\text{ck} \leftarrow \text{Biv.ComGen}(1^\lambda, d, \ell)$, where d, ℓ are the bounds on the degrees on X and Y of the bivariate polynomials in $\mathbb{Z}_q[X, Y]$.

MPoly.Com(ck, $\{P_j\}_{0 \leq j \leq \ell}$) \rightarrow (C, ρ) : Given a set $\{P_j\}$ of $\ell + 1$ polynomials in $\mathbb{Z}_q[X]$, with coefficients $\{p_{ij}\}_{i,j=0}^{i \leq d, j \leq \ell}$ we can define the bivariate polynomial $P = \sum_{i,j=0}^{d,\ell} p_{ij} X^i Y^j$ and run $(C, \rho) \leftarrow \text{Biv.Com}(ck, P)$;

MPoly.ComVer(ck, $C = (c, \hat{c})$) \rightarrow 0/1: Runs $b \leftarrow \text{Biv.ComVer}(ck, C = (c, \hat{c}))$;

MPoly.OpenVer(ck, $C, \{P_j\}_{0 \leq j \leq \ell}, \rho$) \rightarrow $\{P_j\}_j$: Runs $P \leftarrow \text{Biv.OpenVer}(ck, C, P, \rho)$ where P is parsed as $\sum_{i,j=0}^{d,\ell} p_{ij} X^i Y^j$. then output 1, else output 0 (reject).

We state the following theorem. Its proof simply follows from the way we encode multiple polynomials into a bivariate one.

Theorem 11. *This commitment scheme MPoly-Com is perfectly hiding, computationally binding, and knowledge binding assuming the scheme BivPoly.Com also is so.*

Proof. Let us show these three properties from the initial BivPoly.Com commitment.

Perfect hiding: Since $C = (c, \hat{c})$ in \mathbb{G}^2 is generated by Biv.Com algorithm, and BivPoly.Com is hiding, we have that MPoly-Com is perfectly hiding as well.

Computational binding: Assume that there exists a non-uniform probabilistic time adversary \mathcal{A} that given a commitment $C = (c, \hat{c})$ creates two valid openings $(\{A_j\}_j, \rho), (\{B_j\}_j, \tau)$, where all $A_j, B_j \in \mathbb{Z}_q[X]$. Then we create an adversary \mathcal{B} against the binding of BivPoly.Com that runs \mathcal{A} and outputs the pair of polynomials in $\mathbb{Z}_q[X, Y]$ as follows $A := \sum_{j=0}^{\ell} A_j Y^j$ and $B := \sum_{j=0}^{\ell} B_j Y^j$. We have that (A, ρ) and (B, τ) are two valid openings for the commitment C . This breaks the binding property of BivPoly.Com.

Knowledge binding: This property follows directly from the knowledge binding of BivPoly.Com scheme.

7.2 Succinct Proof of Multiple Evaluations in a Point k

The construction of an efficient MUniEv- Π dedicated to multiple uni-variate polynomial evaluations in some common point k follows as well from the BivPE- Π scheme we built for partial evaluations. More precisely, for some parameters d, ℓ and some given knowledge commitments C, C' for polynomials of maximal degree d , $\{P_j\}_{0 \leq j \leq \ell} \in \mathbb{Z}_q[X]$ and scalars $\{p_j\}_{0 \leq j \leq \ell} \in \mathbb{Z}_q$ and a public evaluation point $k \in \mathbb{Z}_q$, we want to prove that p_j is the evaluation $P_j(k)$ for any $0 \leq j \leq \ell$.

Description of Our CaP MUniEv- Π Protocol. We now describe our protocol for proving multiple uni-variate polynomial evaluations in some common point k , where the j index is always considered as $0 \leq j \leq \ell$, and thus for $\ell + 1$ polynomials:

MUniEv- Π .Gen($1^\lambda, \mathcal{R}_{\text{uni}}$) \rightarrow **crs**: On input a security parameter $\lambda \in \mathbb{N}$ and a NP relation $\mathcal{R}_{\text{uni}} := \{(u = (\{P_j\}_j, k); w = \{p_j\}) : P_j(k) = p_j\}$, define the associated relation $\mathcal{R}_{\text{bi}} := \{(u = (P(X, Y), k); w = Q(Y)) : Q(Y) = P(k, Y)\}$ where $P(X, Y) := \sum_{j=0}^{\ell} P_j Y^j$, $Q(Y) := \sum_{j=0}^{\ell} p_j Y^j$. Output the common reference string by running $\text{crs} \leftarrow \text{Gen}(\text{ck}, \mathcal{R}_{\text{bi}})$;

MUniEv- Π .Prove($\text{crs}, u = (C, C', k), w = (\{P_j\}_j, \{p_j\}_j, \rho, \rho')$): Given crs , the instance u and the witness w , the prover defines new bi-variate polynomials $P(X, Y) := \sum_{j=0}^{\ell} P_j Y^j$, $Q(Y) := \sum_{j=0}^{\ell} p_j Y^j$ and compute the proof π for those: $\pi \leftarrow \text{Prove}(\text{crs}, u = (C, C', k), w = (P, Q, \rho, \rho'))$. Output $\pi := (D, e, \sigma, \tau)$;

MUniEv- Π .Ver(crs, u, π) \rightarrow **b**: Same algorithm as for partial-evaluation BivPE- Π .

Remark 12. The commitment D to the bivariate polynomial $W \in \mathbb{Z}_q[X, Y]$ that appears in the proof can be seen as a commitment to a vector of univariate polynomials $\{W_j\}_j$ using the MPoly-Com as follows: Write $W_j = \sum_{i=0}^d w_{ij} X^i$, then running $\text{MPoly.Com}(\text{ck}, \{W_j\}_j)$ gives the same output (D, ω) as running $\text{Biv.Com}(\text{ck}, W)$.

Theorem 13. *Assuming the BivPE- Π is a public coin argument of knowledge of openings of C and C' to some polynomials $P \in \mathbb{Z}_q[X, Y], Q \in \mathbb{Z}_q[Y]$ such that $P(k, Y) = Q(Y)$, then MUniEv- Π is a public coin argument of knowledge of openings of C and C' to a set of polynomials $\{P_j\}_j \in \mathbb{Z}_q[X]$ and a set of scalars $\{p_j\}_j \in \mathbb{Z}_q$ such that $P_j(k) = p_j \forall 0 \leq j < \ell$.*

Proof. We prove the required properties:

Correctness. Follows from the BivPE- Π correctness.

Knowledge Soundness. We first build a knowledge-extractor. This knowledge extractor directly follows from Theorem 14 and an extended extractor can be defined as in Theorem 15. For any adversary \mathcal{B} against BivPE- Π , there exists an aggregated machine \mathcal{B}^* that outputs the same as \mathcal{B} together with a extended witness $\text{wit} = (P, \rho, Q, \rho', W, \omega)$.

From the output of this extended machine \mathcal{B}^* we can further extract $\{P_j := \sum_{i=0}^d p_{ij} X^i\}_j, \{p_j := q_j\}_j, W_j := \sum_{i=0}^d w_{ij} X^i\}_j$ just by reading the respective coefficients p_{ij}, q_j, w_{ij} from the bivariate polynomials $P = \sum_{i,j=0}^{d,\ell} p_{ij} X^i Y^j$, $Q = \sum_{j=0}^{\ell} q_j Y^j$, and $W = \sum_{i,j=0}^{d,\ell} w_{ij} X^i Y^j$.

Therefore, for any adversary \mathcal{A} against the MUniEv- Π protocol, there exists an extended machine \mathcal{A}^* that runs the aggregate machine \mathcal{B}^* under its output and further returns the same statement and proof as \mathcal{A} together with an extended witness $\text{wit} = (\{P_j\}_j, \rho, \{p_j\}_j, \rho', \{W_j\}_j, \omega; \delta, \gamma)$, where $P_j, W_j \in \mathbb{Z}_q[X], p_j \in \mathbb{Z}_q$ are the openings of the commitments (C, C', D) under randomness ρ, ρ', ω and δ, γ are such that $\mathbb{A} = \mathbf{e}(d, \mathbf{g}_1/\mathbf{g}^k) \cdot \mathbf{e}(c/c', \mathbf{g})^{-1} = \mathbf{e}(h^\delta \tilde{g}^\gamma, \mathbf{g})$.

Soundness. We reduce the soundness of MUniEv- Π to the soundness of BivPE- Π . Suppose there exists an adversary \mathcal{A} against the soundness of MUniEv- Π , with the corresponding associated extended machine \mathcal{A}^* that outputs a cheating proof π^* that passes the verification check with non-negligible probability. We then build an efficient adversary \mathcal{B} against BivPE- Π that runs the machine \mathcal{A}^* to break the protocol with non-negligible probability.

\mathcal{B} runs \mathcal{A}^* that outputs the corresponding tuple proof-statement-witness $u = (C, C', k), \pi^* = (D, e, \sigma, \tau), \text{wit} = (\{P_j\}_j, \rho, \{p_j\}_j, \rho', \{W_j\}_j, \omega; \delta, \gamma)$. Then, we can define some corresponding bivariate polynomials as follows and build an extractor for \mathcal{B} : We have the corresponding polynomials $P \in \mathbb{Z}_q[X, Y]$ and $Q \in \mathbb{Z}_q[Y]$ defined from the univariate polynomials extracted above: $P(X, Y) := \sum_{j=0}^{\ell} P_j(X) Y^j, Q(Y) := \sum_{j=0}^{\ell} p_j Y^j$.

We know by our assumption that in the output of \mathcal{A}^* there exists at least one $j_0 \in \{0, \dots, \ell\}$ such that $P_{j_0}(k) \neq p_{j_0}$. Then it follows that the previous defined P and Q do not satisfy the required statement: $P(k, Y) \neq Q(Y)$, which breaks the soundness of the BivPE- Π . \square

7.3 Efficiency and Comparison

We summarize the performance of our scheme MUniEv- Π in terms of prover and verification time and proof size. The proof consists of 2 elements from the group \mathbb{G} and 3 elements of \mathbb{Z}_q . Generating a proof for ℓ polynomials of degree d requires a total of $2\ell d$ exponentiations in \mathbb{G} in order to compute the commitment D , and $O(\ell d \log d)$ operations in \mathbb{Z}_q in order to compute the polynomial $W(X, Y)$ using polynomial division.⁴ Verifying a proof requires 5 pairings, and the following number of exponentiations: 6 in \mathbb{G} , 1 in \mathfrak{G} and 1 in \mathbb{G}_T .⁵

We compare MUniEv- Π against a solution based on a general-purpose SNARK restricted to proving multiple polynomial evaluations in a commit-and-prove fashion. For the latter, we choose the *LegoGroth16* scheme from [CFQ19], which makes the SNARK of [Gro16] (which is currently among the most efficient SNARKs) to efficiently work with committed inputs, and that achieves the following efficiency. The proof consists of 4 elements of \mathbb{G} and 1 element of \mathfrak{G} . Let m and n be the size and degree of the QAP modeling the evaluation of ℓ polynomials of degree d , and note that $m, n \geq \ell d$. Proof generation requires $2m + n + \ell d + \ell$ and m exponentiations in \mathbb{G} and \mathfrak{G} respectively, as well as $O(n \log n)$ operations in \mathbb{Z}_q for a polynomial division. Verification requires 7 pairings.

The analysis above shows that our scheme MUniEv- Π has slightly smaller proofs and, more notably, has faster proof generation. Considering that $m, n \geq \ell d$ and that \mathfrak{G} operations are at least twice slower than in \mathbb{G} , our prover is at least 3 times faster.

⁴ Note that W can be computed by aggregating the results of ℓ polynomial divisions of degree d .

⁵ The numbers are obtained by observing that the six pairings for Biv.ComVer can be batched resulting into 2 pairings and 4 exponentiations in \mathbb{G} .

<u>Prove(crs, u, w)</u>	<u>Sim^{Prove}(crs, u = (C, C', k))</u>
1: $W := (P - Q)/(X - k)$	1: $W^* := 0 \in \mathbb{Z}_q[X, Y]$
2: $(D, \omega) \leftarrow \text{Biv.Com}(W)$	2: $(D^* = (d, \hat{d}), \omega) \leftarrow \text{Biv.Com}(W^*)$
3: $x, y \leftarrow \mathbb{Z}_q$	3: $e, x, y, k \leftarrow \mathbb{Z}_q, \mathbb{A} = \mathbf{e}(d, \mathbf{g}_1/\mathbf{g}^k)\mathbf{e}(c/c', \mathbf{g})^{-1}$
4: $\mathbb{U} := \mathbf{e}(h^x \tilde{g}^y, \mathbf{g})$	4: $\mathbb{U}^* = \mathbf{e}(h^x \tilde{g}^y, \mathbf{g})\mathbb{A}^e$
5: $e \leftarrow \text{Hash}(u, D, \mathbb{U})$	5: If $\text{Hash}(u, D^*, \mathbb{U}^*) \in \text{Query}$, abort Else, $\text{Hash}(u, D^*, \mathbb{U}^*) := e$

8 Security Analysis of our CaP BivPE- Π

In what follows we prove the main security result of our paper, Theorem 10.

Correctness. Correctness of our protocol can be proved by direct verification: if the commitments C, C', D are honestly generated, the checks the **Ver** algorithm does all pass through. We consider $C = h^\rho g^{P(s,t)}, C' = h^{\rho'} g^p, D = h^\omega g^{W(s)}$, where $Q = P(k, Y)$ and $W(X, Y) = \frac{P(X, Y) - P(k, Y)}{(X - k)}$. We have that $\mathbb{U} := \mathbf{e}(h^x \tilde{g}^y, \mathbf{g})$ and the verifier computes \mathbb{U} from u and π as follows:

$$\begin{aligned}
\mathbb{U} &= \mathbf{e}(h^\sigma \tilde{g}^\tau, \mathbf{g}) \cdot \mathbb{A}^e = \mathbf{e}(h^\sigma \tilde{g}^\tau, \mathbf{g}) \cdot \mathbf{e}(d, \mathbf{g}_1/\mathbf{g}^k)^e \cdot \mathbf{e}(c/c', \mathbf{g})^{-e} \\
&= \mathbf{e}(h^\sigma \tilde{g}^\tau, \mathbf{g}) \cdot \mathbf{e}(h^\omega g^{W(s)}, \mathbf{g}^{s-k})^e \cdot \mathbf{e}(h^{\rho-\rho'} g^{P(s,t)-p}, \mathbf{g})^{-e} \\
&= \mathbf{e}(h^\sigma \tilde{g}^\tau, \mathbf{g}) \cdot \mathbf{e}(h, \mathbf{g})^{e(s-k)\omega} \cdot \mathbf{e}(g, \mathbf{g})^{e(s-k)W(s)} \cdot \mathbf{e}(h, \mathbf{g})^{e(\rho'-\rho)} \cdot \mathbf{e}(g, \mathbf{g})^{-e(P(s,t)-p)} \\
&= \mathbf{e}(h^\sigma \tilde{g}^\tau, \mathbf{g}) \cdot \mathbf{e}(h, \mathbf{g})^{e(s-k)\omega + e(\rho'-\rho)} = \mathbf{e}(h^\sigma \tilde{g}^\tau, \mathbf{g}) \cdot \mathbf{e}(h^{e(\rho'-\rho)} \tilde{g}^{e\omega}, \mathbf{g}) = \mathbf{e}(h^x \tilde{g}^y, \mathbf{g}).
\end{aligned}$$

Zero-Knowledge. We consider the case of a honest verifier **Ver** to prove zero-knowledge of our scheme, as we use the Fiat-Shamir heuristic to convert it into a non-interactive proof [PS00]. We thus have to construct a simulator $\text{Sim} = (\text{Sim}^{\text{crs}}, \text{Sim}^{\text{Prove}})$, where Sim^{crs} is the same as **Gen** algorithm and outputs $(\text{crs}, \text{trap} := \perp)$. $\text{Sim}^{\text{Prove}}$ is able to generate a simulated proof for any commitments C, C' and any k by committing any W^* (we can use $W^* := 0$) and then simulating the Schnorr's proof. We proceed with a sequence of games in order to show the indistinguishability of the simulation.

Hybrid 0. This is the real protocol, described in Figure 5, where proof π is generated by **Prove** algorithm.

Hybrid 1. In this game, we use the witness of the evaluation, $w = (P, Q, \rho, \rho')$, and we generate $W \in \mathbb{Z}_q[X, Y]$ as in step 1 of the real protocol, but in order to generate the proof π , we run instead the zero-knowledge simulator of the Schnorr proof (as in the lines 4 to 8 in $\text{Sim}^{\text{Prove}}$ procedure). Based on the fact that x, y are picked uniformly at random, \mathbb{U} is uniformly random as well and the probability that the value (u, D, \mathbb{U}) had already been queried to the **Hash** oracle is q_h/q , where q_h is the number of queries asked to the oracle and q is the order of the group. It follows that the probability of this simulator to be distinguishable from the real proof algorithm is as well negligible.

Hybrid 2. The $\text{Sim}^{\text{Prove}}$ algorithm described in Figure 5 outputs the proof. Based on the perfectly hiding property of the commitment scheme the values D^* and D in the two hybrids 1 and 2 are indistinguishable.

Knowledge Soundness. Before going into the technical details of the proof, we provide some intuition about its strategy. The polynomial commitment scheme **BivPoly.Com** requires the prover **Prove** to exhibit two values (c, \hat{c}) , that are the same encoding of coefficients of a polynomial $P(X, Y)$ in the exponent, but with respect to different bases. The reason that we require the

prover to duplicate its effort w.r.t. α is so that the simulator in the security proof can extract representations of (c, \hat{c}) as a polynomial $P(X, Y)$, under the (d, ℓ) – BPKE assumption.

Suppose an adversary \mathcal{A} manages to forge a SNARK of a false statement that nonetheless passes the verification test. The intuition behind the proof is to use the adversary \mathcal{A} and the fact that the commitment scheme BivPoly.Com is extractable to be able to solve the d – SDH assumption for $d = \deg(P)$ in X . There is a similar complementary case that allows this adversary to solve the d – SDH assumption for $d = \deg(P)$ in Y (actually ℓ in our notations).

To proceed to proving Theorem 10, we first need two preliminary lemmas:

Lemma 14 (Global Extractor). *Assume that BivPoly.Com is an extractable commitment scheme with perfect hiding and computational binding properties and that (d, ℓ) –BPKE assumption holds in the bilinear group gk . For any PPT adversary \mathcal{A}^{KS} against the knowledge soundness of $\text{BivPE-}\Pi$ that has non-negligible probability of success in breaking the scheme, there exists an extractor Ext such that:*

$$\Pr \left[\begin{array}{l} C = \text{Biv.Com}(P, \rho) \\ \wedge C' = \text{Biv.Com}(Q, \rho') \\ \wedge D = \text{Biv.Com}(W, \omega) \end{array} \middle| \begin{array}{l} \text{crs} \leftarrow \text{BivPE-}\Pi.\text{Gen}(1^\lambda, \mathcal{R}), z \leftarrow \mathcal{Z}(\text{crs}) \\ ((u, \pi); \text{wit}) \leftarrow (\mathcal{A}^{\text{KS}} \parallel \text{Ext}^*)(\text{crs}, z) \\ u := (C, C', k), \pi := (D, \mathbb{U}, \sigma, \tau) \\ \text{wit} := (P, \rho, Q, \rho', W, \omega) \\ \text{BivPE-}\Pi.\text{Ver}(\text{crs}, u, \pi) = 1 \end{array} \right] = \\ = 1 - \text{negl}(\lambda).$$

Proof. We show the existence of an extractor Ext^* that will output the polynomials $P(X, Y)$, $Q(Y)$, $W^*(X, Y)$ and the randomness ρ, ρ', ω corresponding to the commitments C, C', D , with overwhelming probability.

Let \mathcal{A}^{KS} be an adversary that breaks the KS of the protocol $\text{BivPE-}\Pi$ with overwhelming probability, meaning it outputs a false proof that passes the verifier checks. Consider now the adversary $\mathcal{B}^{\text{BPKE}}$ that takes as input $\sigma \leftarrow (g, \{g^{s^{ij}}\}_{i,j=0}^{d,\ell}, \{\hat{g}^{s^{ij}}\}_{i,j=0}^{d,\ell}; (h, \hat{h}, h^s); (\mathbf{g}, \mathbf{g}^\alpha, \mathbf{g}^s))$ and runs the adversary \mathcal{A}^{KS} against the scheme. $\mathcal{B}^{\text{BPKE}}$ can provide a valid CRS to \mathcal{A}^{KS} by using its inputs:

$$\text{crs} = \{\text{gk}, (g_{ij})_{i,j=0}^{d,\ell}, (\hat{g}_{ij})_{i,j=0}^{d,\ell}; (h, \hat{h}, h_1); (\mathbf{g}, \mathbf{g}^\alpha, \mathbf{g}_1)\}.$$

The statement u , corresponding to $\pi \leftarrow \mathcal{A}^{\text{KS}}(\text{crs})$, contains the values $C := (c, \hat{c}), C' := (c', \hat{c}')$ that verify $e(c, \hat{\mathbf{g}}) = e(\hat{c}, \mathbf{g})$ and $e(c', \hat{\mathbf{g}}) = e(\hat{c}', \mathbf{g})$. The same holds for the value D provided in the proof $\pi = (D, e, \sigma, \tau)$, i.e. $e(d, \hat{\mathbf{g}}) = e(\hat{d}, \mathbf{g})$.

Provided that for any adversary $\mathcal{B}^{\text{BPKE}}$ that outputs valid commitment pair (c, \hat{c}) , there exists an extractor that returns the corresponding witness (the opening). We run the extractor $\text{Ext}_{\mathcal{B}}$ associated to $\mathcal{B}^{\text{BPKE}}$ for each of the inputs $C = (c, \hat{c}), C' = (c', \hat{c}'), D = (d, \hat{d})$. This returns the description of polynomials $P(X, Y), Q(Y), W^*(X, Y)$ and some scalars ρ, ρ', ω . Note that the existence and efficacy of $\text{Ext}_{\mathcal{B}}$ is guaranteed by the (d, ℓ) – BPKE assumption. We will then define a *general* extractor Ext^* associated to the adversary \mathcal{A}^{KS} by running $\text{Ext}_{\mathcal{B}}$ on the same input. We call this global algorithm composed of the adversary \mathcal{A}^{KS} and the general extractor Ext^* , machine $M := \mathcal{A}^{\text{KS}} \parallel \text{Ext}^*$. \square

Lemma 15 (Extended Adversary Machine). *Assume that (d, ℓ) – BPKE assumption holds in the bilinear group gk and that Schnorr proof used in the $\text{BivPE-}\Pi$ protocol is sound. For any PPT adversary \mathcal{A}^{KS} against the knowledge soundness of the scheme $\text{BivPE-}\Pi$ that outputs $u = (C, C', k), \pi = (D, e, \sigma, \tau)$, where C, C', D are well-formed commitments under BivPoly.Com and the proof π verifies, i.e. $\text{Ver}(\text{crs}, u, \pi)$, there exists a machine, extended adversary \mathcal{A}^* that outputs the same as \mathcal{A}^{KS} together with an extended witness $\text{wit} = (P, \rho, Q, \rho', W, \omega, \delta, \gamma)$, where $P, W \in \mathbb{Z}_q[X, Y], Q \in \mathbb{Z}_q[Y]$ are the openings of the commitments (C, C', D) under randomness ρ, ρ', ω and δ, γ are such that $\mathbb{A} = e(d, \mathbf{g}_1/\mathbf{g}^k) \cdot e(c/c', \mathbf{g})^{-1} = e(h^\delta \tilde{g}^\gamma, \mathbf{g})$.*

Proof. We use the previous defined machine M from Theorem 14 and the rewinding technique [PS00] for proving the soundness of the Schnorr's proof to extract the scalars δ, γ such that $\mathbb{A} = \mathbf{e}(h^\delta \tilde{g}^\gamma, \mathbf{g})$: Consider the game between the challenger and the machine M against the soundness of the Schnorr's proof. The challenger runs M by fixing the values (C, C', D) and changing the oracle definition to get a fork with $e' \leftarrow \text{Hash}(U, D, \mathbb{U}) \neq e$. The forger M will output two distinct forgeries corresponding to the same random oracle query, but for two distinct answers of the random oracle, e and e' . The Forking Lemma shows that by rewinding the adversary $\mathcal{O}(q_h/\varepsilon)$ times, where q_h is the maximal number of random oracle queries of the machine M and ε its success probability, then one finds two such forgeries $(\sigma, \tau), (\sigma', \tau')$ with constant probability, which enables to compute the values δ, γ such that $\mathbb{A} = \mathbf{e}(h^\delta \tilde{g}^\gamma, \mathbf{g})$.

Using the existence of Ext^* extractor and of the algorithm that rewinds the machine M in order to obtain the output δ, γ as described before, we can define an aggregate machine \mathcal{A}^* corresponding to the concatenation of both. This machine \mathcal{A}^* takes the same input as \mathcal{A}^{KS} and outputs the witness corresponding to the commitment openings $(P, \rho), (Q, \rho'), (W, \omega)$ and two scalars δ, γ satisfying $\mathbb{A} = \mathbf{e}(h^\delta \tilde{g}^\gamma, \mathbf{g})$. \square

Knowledge Soundness. We now have all the tools to prove the soundness in two steps.

Step 1. First we show that for every PPT adversary \mathcal{A}^{KS} against the soundness of the protocol, there exists an extractor $\text{Ext}_{\mathcal{A}}$ that runs on the same input and random coins as \mathcal{A}^{KS} and outputs a witness. Defining the extractor $\text{Ext}_{\mathcal{A}}$ is straightforward from the Theorem 14 by running the Ext^* and keeping just the values (P, ρ, Q, ρ') from its output.

Assuming the existence of an adversary \mathcal{A}^{KS} and extractor $\text{Ext}_{\mathcal{A}}$ that has a non-negligible success probability in winning the soundness game against the protocol $\text{BivPE-}\Pi$, we now show that we can either solve the discrete logarithm problem, or break the $d - \text{SDH}$ assumption.

Step 2. Suppose the machine \mathcal{A}^* associated to \mathcal{A}^{KS} defined in the Theorem 15 is able to output a cheating pair statement-proof $u = (C, C', k), \pi = (D, e, \sigma, \tau)$ and a witness $\text{wit} = (\rho, \rho', \omega, P, Q^*, W^*, (\delta, \gamma))$ such that it passes verification checks, but the extracted values $P \in \mathbb{Z}_q[X, Y], Q^* \in \mathbb{Z}_q[Y]$ are not satisfying the expected relation $Q^*(Y) = P(k, Y)$.

For simplicity, we will call $\Delta = \rho' - \rho$. Assuming that the commitment scheme is binding, then one of the following scenarios must hold:

1. The polynomials extracted do not satisfy the correct relation not even when evaluated in s : $W^*(s, t) \neq \frac{P(s, t) - Q^*(t)}{s - k}$. This type of forgery can be reduced to the DLog problem for $(g, h) \in \mathbb{G}$, in the case 1 below (see Theorem 16);
2. The polynomial $W^* \in \mathbb{Z}_q[X, Y]$ committed in D does not satisfy the correct relation with respect to the other extracted values P, Q^* , but still evaluated in s, t we have that $W^*(s, t) = \frac{P(s, t) - Q^*(t)}{s - k}$. We reduce the case to the $d - \text{SDH}$ assumption, in the case 2 below (see Theorem 17).

\square

Lemma 16 (Case 1). *Consider the adversarial machine \mathcal{A}^* associated to \mathcal{A}^{KS} defined by the Theorem 15 that outputs some values $u = (k, C, C', D, e, \sigma, \tau)$ and $(\rho, P, \rho', Q^*, \omega, W^*, \delta, \gamma)$, such that $P(k, Y) \neq Q^*(Y)$, where $P, W^* \in \mathbb{Z}_q[X, Y], Q^* \in \mathbb{Z}_q[Y]$ and $(P, \rho), (Q^*, \rho'), (W^*, \omega)$ are the openings of the commitments (C, C', D) and (δ, γ) satisfy $\mathbb{A} := \mathbf{e}(h^\omega g^{W^*(s, t)}, \mathbf{g}_1/\mathbf{g}^k) \cdot \mathbf{e}(h^{-\Delta} g^{P(s, t) - Q^*(t)}, \mathbf{g})^{-1} = \mathbf{e}(h^\delta \tilde{g}^\gamma, \mathbf{g})$. Given that the verification check outputs 1 for π , there is a negligible probability that the values k, P, Q^*, W^* are such that $W^*(s, t) \neq \frac{P(s, t) - Q^*(t)}{(s - k)}$ under DLog assumption with respect to the group \mathbb{G} .*

Proof. Let $\mathcal{B}^{\text{DLog}}$ be an adversary that gets the challenge $(g, h) \in \mathbb{G}$ and simulates the crs to \mathcal{A}^* by picking $\alpha, s \in \mathbb{Z}_p$ and computing the missing elements. We define $\tilde{g} := h^{s-k}$, and we denote δ, γ , the two outputs of \mathcal{A}^* such that $\mathbb{A} = \mathbf{e}(h^\delta \tilde{g}^\gamma, \mathbf{g})$. Assuming the binding of the commitment

scheme, the check in the verification step of the scheme gives us: $e(h^{(s-k)\omega} g^{(s-k)W^*(s,t)}, \mathfrak{g}) \cdot e(h^{\rho-\rho'} g^{P(s,t)-Q^*(t)}, \mathfrak{g})^{-1} = e(h^\delta \tilde{g}^\gamma)$. By the non-degeneracy of the pairing map, it must be that

$$h^{\delta+(s-k)\gamma-\Delta-(s-k)\omega} = g^{(s-k)W^*(s,t)-P(s,t)+Q^*(t)}.$$

Since $(s-k)W^*(s,t) - P(s,t) + Q^*(t) \neq 0$, we can extract the discrete logarithm of h in basis g . \square

Lemma 17 (Case 2). *Consider the adversarial machine \mathcal{A}^* associated to \mathcal{A}^{KS} defined by the Theorem 15 that outputs some values $u = (k, C, C', D, e, \sigma, \tau)$ and $(\rho, P, \rho', Q^*, \omega, W^*, \delta, \gamma)$, such that $P(k, Y) \neq Q^*(Y)$, where $P, W^* \in \mathbb{Z}_q[X, Y]$, $Q^* \in \mathbb{Z}_q[Y]$ and $(P, \rho), (Q^*, \rho'), (W^*, \omega)$ are the openings of the commitments (C, C', D) and (δ, γ) satisfy $\mathbb{A} := e(h^\omega g^{W^*(s,t)}, \mathfrak{g}_1/\mathfrak{g}^k) \cdot e(h^{-\Delta} g^{P(s,t)-Q^*(t)}, \mathfrak{g})^{-1} = e(h^\delta \tilde{g}^\gamma, \mathfrak{g})$. Given that the verification check outputs 1 for π , there is a negligible probability that the values k, P, Q^*, W^* satisfy $W^*(s, t) = \frac{P(s,t)-Q^*(t)}{(s-k)}$ under $d' - \text{SDH}$ assumption with respect to the bilinear group \mathfrak{gk} , where $d' = \max\{d, \ell\}$.*

Proof. Consider the adversary \mathcal{B}^{SDH} against $d' - \text{SDH}$ assumption, having as auxiliary input $z = (k, \Delta, \omega, \delta, \gamma)$. Using its challenge $(g, g^s, \dots, g^{s^d}, \hat{g}^s, \dots, \hat{g}^{s^d}; h, h^s, \hat{h}; (\mathfrak{g}, \mathfrak{g}^s))$ it picks random scalars $\alpha, t \leftarrow \mathbb{Z}_q$ and computes $g_{ij} := g^{s^i t^j}$, $\mathfrak{g}_{ij} := \mathfrak{g}^{s^i t^j}$ for $i = 0, \dots, d$ and $j = 0, \dots, \ell$, $\hat{\mathfrak{g}} := \mathfrak{g}^\alpha$, and computes a commitment key $\text{ck} = \{\mathfrak{gk}, (g_{ij})_{i,j=0}^{d,\ell}, (\hat{g}_{ij})_{i,j=0}^{d,\ell}; (h, \hat{h}); (\mathfrak{g}, \hat{\mathfrak{g}})\}$. It further sends the following crs corresponding to the relation \mathcal{R}_{ck} to \mathcal{A}^* : $\text{crs} = \{\text{ck}, (h_1, \mathfrak{g}_1), \text{Hash}(\cdot, \cdot, \cdot)\}$. Note that h_1 and \mathfrak{g}_1 are in the initial challenge.

From the output of the aggregated machine \mathcal{A}^* , \mathcal{B}^{SDH} gets the values $u = (k, C, C', D, e, \sigma, \tau)$ and $(\rho, P, \rho', Q^*, \omega, W^*, \delta, \gamma)$. The verification check of the Schnorr proof implies

$$\begin{aligned} \mathbb{A} &= e(d, \mathfrak{g}_1/\mathfrak{g}^k) \cdot e(c/c', \mathfrak{g})^{-1} = e(h^\omega g^{W^*(s,t)}, \mathfrak{g}^{s-k}) \cdot e(h^{-\Delta} g^{P(s,t)-Q^*(t)}, \mathfrak{g})^{-1} \\ &= e(h^\Delta h^{(s-k)\omega}, \mathfrak{g}) \cdot e(g^{-(P(s,t)-Q^*(t))} g^{(s-k)W^*(s,t)}, \mathfrak{g}) = e(h^\Delta \tilde{g}^\omega, \mathfrak{g}). \end{aligned}$$

The outputs δ, γ from the extended adversary machine are such that $\mathbb{A} = e(h^\delta \tilde{g}^\gamma, \mathfrak{g})$ (from the soundness of the Schnorr's proof). This, together with the previous equation leads to the conclusion $e(h^\delta \tilde{g}^\gamma, \mathfrak{g}) = e(h^\Delta \tilde{g}^\omega, \mathfrak{g})$ and so $e(h^{\Delta-\delta} \tilde{g}^{\omega-\gamma}, \mathfrak{g}) = 1$. The adversary \mathcal{B}^{SDH} is able to produce a solution to the equation $(s-k)(\omega-\gamma) + \Delta - \delta = 0 \pmod q$ and though to find $s = k + \frac{\delta-\Delta}{\omega-\gamma} \pmod q$, unless $\gamma = \omega$ and $\delta = \Delta$.

In the former case, from the value s , one can easily break any SDH problem. In the latter case, the two writings for \mathbb{A} , and the non-degeneracy of the pairing map lead to $g^{(s-k)W^*(s,t)-P(s,t)+Q^*(t)} = 1$.

Using $P \in \mathbb{Z}_q[X, Y]$, compute $Q(Y) := P(k, Y)$ and define the polynomial $W = \frac{P(X,Y)-Q(Y)}{(X-k)} \in \mathbb{Z}_q[X, Y]$. We have also that $g^{(s-k)W(s,t)} = g^{P(s,t)-Q(t)}$, then $\mathcal{B}^{d'-\text{SDH}}$ computes $g^{Q(t)-Q^*(t)} = g^{(s-k)(W^*(s,t)-W(s,t))}$. Define the polynomial in $\mathbb{Z}_q[X, Y]$: $W'(X, Y) = (X-Y)(W(X, Y) - W^*(X, Y)) - Q(Y) + Q^*(Y)$, we have that $g^{W'(s,t)} = 1$. This splits in two cases:

1. If $W'(X, t) = \sum_i (\sum_j w'_{ij} t^j) X^i$ is the zero polynomial in X , meaning that all the coefficients $\tilde{w}_i = \sum_j w'_{ij} t^j$ are zero $\forall i \in \{0, \dots, d\}$, then by choosing an index $i_0 \in \{0, \dots, d\}$ with a non-zero element $w'_{i_0 j}$ (unless $W' = 0$ which contradicts the hypothesis of the Lemma) we have that t is a root of the polynomial $\sum_j w'_{i_0 j} Y^j$.
2. If there exists at least one index \tilde{i} , such that $\tilde{w}_{\tilde{i}} = \sum_j w'_{\tilde{i} j} t^j \neq 0$, then we have that s is a root of the polynomial defined by fixing t : $W'(X, t) = \sum_i \tilde{w}_i X^i$.

If the first case happens with non-negligible probability, algorithm $\mathcal{B}_1^{\text{SDH}}$ receives an $\ell - \text{SDH}$ instance in t , and choosing s , can complete the input for the aggregate machine \mathcal{A}^* . Knowing that $\sum_j w'_{i_0 j} t^j = 0$, the adversary $\mathcal{B}_1^{\text{SDH}}$ is able to compute $g^{\frac{1}{t}}$ in the following way: Consider $w'_{i_0 j_0}$ the first non-zero coefficient of the polynomial $\sum_j w'_{i_0 j} Y^j$: $g^{w'_{i_0 j_0} t^{j_0}} = g^{t^{j_0+1} W''(t)}$ for some

polynomial W'' of lower degree, and so $g^{w'_{i_0j_0}} = g^{tW''(t)}$, or equivalently $g^{1/t} = (g^{W''(t)})^{1/w'_{i_0j_0}}$. $\mathcal{B}_1^{\text{SDH}}$ is then able to solve the ℓ -SDH problem, as $g^{W''(t)}$ can be computed from the initial instance.

If the second case happens with non-negligible probability, the algorithm $\mathcal{B}_2^{\text{SDH}}$ receives a d -SDH instance in s , and can complete it as an input for \mathcal{A}^* by choosing t . Doing as above, with a polynomial that has s as a root, it can compute $g^{1/s}$. This solves the ℓ -SDH instance. \square
